

Higher Arf Functions and Moduli Space of Higher Spin Surfaces

Sergey Natanzon and Anna Pratoussevitch*

Communicated by Ernest B. Vinberg

Abstract. We describe all connected components of the space of pairs (P, s) , where P is a hyperbolic Riemann surface with finitely generated fundamental group and s is an m -spin structure on P . We prove that any connected component is homeomorphic to a quotient of \mathbb{R}^d by a discrete group.

Our method is based on a description of an m -spin structure by an m -Arf function, that is a map $\sigma : \pi_1(P, p) \rightarrow \mathbb{Z}/m\mathbb{Z}$ with certain geometric properties. We prove that the set of all m -Arf functions has a structure of an affine space associated with $H_1(P, \mathbb{Z}/m\mathbb{Z})$. We describe the orbits of m -Arf functions under the action of the group of homotopy classes of surface autohomeomorphisms. Natural topological invariants of an orbit are the unordered set of values of the m -Arf functions on the punctures and the unordered set of values on the m -Arf function on the holes. We prove that for $g > 1$ the space of m -Arf functions with prescribed genus and prescribed (unordered) sets of values on punctures and holes is either connected or has two connected components distinguished by the Arf invariant $\delta \in \{0, 1\}$. (See the results for $g = 1$ later in the paper.)

Key Words and Phrases: Higher spin surfaces, Arf functions, lifts of Fuchsian groups.

1. Introduction

In this paper we study m -spin structures, i.e. complex line bundles such that the m -th tensor power is isomorphic to the cotangent bundle of the surface, on hyperbolic Riemann surfaces with finitely generated fundamental group.

The classical spin structures (theta characteristics) on compact Riemann surfaces play an important role in algebraic geometry since Riemann [12]. Their modern interpretation and classification as complex line bundles such that the tensor square is isomorphic to the cotangent bundle of the surface was given by Atiyah [9] and Mumford [10], a topological interpretation of their results was given

*Research partially supported by grants INTAS 05-7805, RFBR-07-01-00593, NSh-709.2008.1, NWO-RFBR 047.011.2004.026 (RFBR: 05-02-89000-HBO_a), and SFB 611 (DFG)

by Johnson [11]. They showed a connection between the set of spin bundles on a surface P and the affine space of quadratic (with respect to the index of intersection) forms $H_1(P; \mathbb{Z}_2) \rightarrow \mathbb{Z}_2$. (Here $\mathbb{Z}_m = \mathbb{Z}/m\mathbb{Z}$.) Classification of classical spin structures on non-compact Riemann surfaces and the corresponding moduli space were studied in [7, 6].

We consider the moduli space of m -spin structures on Riemann surfaces, that is the space of pairs (P, s) , where P is a Riemann surface and s is an m -spin structure on P . This moduli space plays an important role in mathematical physics [8, 15] and singularity theory [3]. The number of connected components of the moduli space of m -spin structures on Riemann surfaces with punctures (but without holes) was determined in [14], using an interpretation of the quotients of m -spin structures on P as points of the Jacobian of P .

Our method uses Fuchsian groups and allows us to work with the fundamental group of the surface rather than with the homology group. We assign to any m -spin structure a set of topological invariants that describes the behavior of the m -spin structure on the basis of the fundamental group. We then show that this set of topological invariants determines a connected component of the moduli space of m -spin structures. Moreover we prove that any connected component is homeomorphic to the space of the form \mathbb{R}^d/Mod , where Mod is a discrete group acting on \mathbb{R}^d .

The main technical tool is the following: We assign (Theorem 4.9) to any m -spin structure on a surface P a unique function on the space of homotopy classes of simple contours on P with values in \mathbb{Z}_m , the associated m -Arf function. In contrast with the case of classical spin structures on compact Riemann surfaces these functions are not commutative and do not induce quadratic forms on the homology group. For this reason some of the proofs are more computational and less geometrical than Johnson's results in [11].

The m -Arf functions are described by simple geometric properties:

Definition: We denote by $\pi_1^0(P, p)$ the set of all non-trivial elements of $\pi_1(P, p)$ that can be represented by simple contours. An m -Arf function is a function

$$\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}_m$$

satisfying the following conditions

1. $\sigma(bab^{-1}) = \sigma(a)$ for any elements $a, b \in \pi_1^0(P, p)$,
2. $\sigma(a^{-1}) = -\sigma(a)$ for any element $a \in \pi_1^0(P, p)$,
3. $\sigma(ab) = \sigma(a) + \sigma(b)$ for any elements a and b which can be represented by a pair of simple contours in P intersecting in exactly one point p with $\langle a, b \rangle \neq 0$,
4. $\sigma(ab) = \sigma(a) + \sigma(b) - 1$ for any elements $a, b \in \pi_1^0(P, p)$ such that the element ab is in $\pi_1^0(P, p)$ and the elements a and b can be represented by a pair of simple contours in P intersecting in exactly one point p with $\langle a, b \rangle = 0$ and placed in a neighborhood of the point p as shown in Figure 4.

In order to formulate our main results we need to give some definitions and notation. We say that a hyperbolic Riemann surface is of type (g, l_h, l_p) if the surface is obtained from a surface of genus g by removing l_h disks and l_p points.

Definition: Let P be a hyperbolic Riemann surface of type (g, l_h, l_p) . Let $\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}_m$ be an m -Arf function on P . For $g > 1$ and even m the Arf invariant $\delta = \delta(P, \sigma)$ of the m -Arf function σ equals zero if there is a standard basis

$$\{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\}$$

of the fundamental group $\pi_1(P, p)$ (compare to Definition 3.7) such that

$$\sum_{i=1}^g (1 - \sigma(a_i))(1 - \sigma(b_i)) = 0 \pmod 2$$

and equals one otherwise. For $g > 1$ and odd m we set $\delta = 0$. (For $g = 1$, see the definition of the Arf invariant later in the paper.) The type of the m -Arf function σ is the tuple

$$(g, \delta, n_0^h, \dots, n_{m-1}^h, n_0^p, \dots, n_{m-1}^p),$$

where δ is the Arf invariant of σ , and n_j^h resp. n_j^p for $j \in \mathbb{Z}_m$ is the number of holes resp. punctures, such that the Arf function σ attains the value j on the corresponding element of the standard basis.

Definition: We denote by

$$S_{g, l_h, l_p}^m(t) = S_{g, l_h, l_p}^m(g, \delta, n_0^h, \dots, n_{m-1}^h, n_0^p, \dots, n_{m-1}^p)$$

the set of all m -spin structures on Riemann surfaces of type (g, l_h, l_p) such that the associated m -Arf function is of type $t = (g, \delta, n_0^h, \dots, n_{m-1}^h, n_0^p, \dots, n_{m-1}^p)$. Here

$$l_h = \sum_{j \in \mathbb{Z}_m} n_j^h \quad \text{and} \quad l_p = \sum_{j \in \mathbb{Z}_m} n_j^p.$$

The following Theorem summarizes the main results:

Theorem 1.1.

- 1) *Two m -spin structures are in the same connected component of the space of all m -spin structures on hyperbolic Riemann surfaces iff they are of the same type. In other words, the connected components of the space of all m -spin structures are those sets $S_{g, l_h, l_p}^m(t)$ that are not empty.*
- 2) *The set $S_{g, l_h, l_p}^m(t)$ is not empty iff $t = (g, \delta, n_0^h, \dots, n_{m-1}^h, n_0^p, \dots, n_{m-1}^p)$ has the following properties:*
 - (a) *If $g > 1$ and m is odd, then $\delta = 0$.*
 - (b) *If $g > 1$ and m is even and $n_j^h + n_j^p \neq 0$ for some even $j \in \mathbb{Z}_m$, then $\delta = 0$.*
 - (c) *If $g = 1$ then δ is a divisor of m and $\gcd(\{j + 1 \mid n_j^h + n_j^p \neq 0\})$.*

(d) *The following degree condition is satisfied*

$$\sum_{j \in \mathbb{Z}_m} j \cdot (n_j^h + n_j^p) = (2 - 2g) - (l_h + l_p).$$

3) *Any connected component $S_{g, l_h, l_p}^m(t)$ of the space of all m -spin structures on hyperbolic Riemann surfaces of type (g, l_h, l_p) is homeomorphic to a quotient of the space $\mathbb{R}^{6g+3l_h+2l_p-6}$ by a discrete action of a certain subgroup of the modular group (see section 5 for details).*

Let us outline the main ideas and methods of the proof. We use the higher Arf functions to describe the topology of the moduli space of m -spin bundles.

We first outline the construction assigning an m -Arf function to an m -spin structure on $P = \mathbb{H}/\Gamma$, where \mathbb{H} is the hyperbolic plane and Γ is a Fuchsian group without elliptic elements. The construction is based on the topological properties of the group $\mathrm{PSL}(2, \mathbb{R}) \cong \mathrm{Aut}(\mathbb{H})$. This group has a unique connected m -fold covering $G_m \rightarrow \mathrm{PSL}(2, \mathbb{R})$. Thereby there is a 1-1-correspondence between m -spin structures on $P = \mathbb{H}/\Gamma$ and lifts into G_m of the group Γ , i.e. subgroups Γ^* of G_m such that the restriction of the covering map $G_m \rightarrow \mathrm{PSL}(2, \mathbb{R})$ to Γ^* is an isomorphism $\Gamma^* \rightarrow \Gamma$ [13]. We prove that the preimage in G_m of the set of all hyperbolic and parabolic elements of $\mathrm{PSL}(2, \mathbb{R})$ has m connected components, which we identify with elements of the group \mathbb{Z}_m . This correspondence induces a map $\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}_m$. The geometric properties of this map follow from the discreteness criterion [6] for subgroups of $\mathrm{PSL}(2, \mathbb{R})$.

We prove that the set of all such functions has a structure of an affine space associated with $H^1(P; \mathbb{Z}_m)$. We describe the orbits of m -Arf functions under the action of the group of homotopy classes of surface autohomeomorphisms. Natural topological invariants of an orbit are the unordered sets of values of the m -Arf functions on the punctures resp. holes. We prove (in the case $g > 1$) that the space of m -Arf functions with prescribed genus and prescribed (unordered) sets of values on punctures resp. holes is either connected or has two connected components distinguished by the Arf invariant $\delta \in \{0, 1\}$.

The paper is organized as follows: In section 2 we study the covering groups G_m of the group $\mathrm{PSL}(2, \mathbb{R})$, and in particular the algebraic properties of the preimages in G_m of hyperbolic and parabolic elements of $\mathrm{PSL}(2, \mathbb{R})$. In section 3 we explore the connection between m -spin structures on a Riemann surface $P = \mathbb{H}/\Gamma$ and lifts into the covering G_m of the group Γ . We assign to any lift a function induced by a decomposition of the covering G_m into sheets and choosing a numeration of the sheets and study properties of these functions. In section 4 we define m -Arf functions. We prove that there is a 1-1-correspondence between the set of m -Arf functions on $P = \mathbb{H}/\Gamma$ and the set of functions associated to the lifts of Γ via the numeration of the covering sheets. Hence these two sets are also in 1-1-correspondence with the set of m -spin structures on P . Moreover we show in this section using the explicit description of the Dehn generators of the group of homotopy classes of surface autohomeomorphisms that the set of all m -Arf functions on a surface P has a structure of an affine space. In the last section

we find topological invariants of m -Arf functions and prove that they describe the connected components of the moduli space. Furthermore we show using a version of Theorem of Fricke and Klein that any connected component is homeomorphic to the space of the form \mathbb{R}^d/Mod , where Mod is a discrete group acting on \mathbb{R}^d .

Part of this work was done during the stays at Max-Planck-Institute in Bonn and at IHES. We are grateful to the both institutions for their hospitality and support. We would like to thank E.B. Vinberg for many useful discussions related to this work. We would like to thank the referees for their valuable remarks and suggestions.

2. The group $\text{PSL}(2, \mathbb{R})$ and its coverings

We consider the universal cover $\tilde{G} = \widetilde{\text{PSL}}(2, \mathbb{R})$ of the Lie group

$$G = \text{PSL}(2, \mathbb{R}) = \text{SL}(2, \mathbb{R})/\{\pm 1\},$$

the group of orientation-preserving isometries of the hyperbolic plane. Here our model of the hyperbolic plane is the upper half-plane $\mathbb{H} = \{z \in \mathbb{C} \mid \text{Im}(z) > 0\}$ and the action of an element $[(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix})] \in \text{PSL}(2, \mathbb{R})$ on \mathbb{H} is by

$$z \mapsto \frac{az + b}{cz + d}.$$

Here we denote by $[A] = [(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix})] \in \text{PSL}(2, \mathbb{R})$ the equivalence class of a matrix $A = (\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}) \in \text{SL}(2, \mathbb{R})$.

Notation. $\mathbb{S}^1 = \{z \in \mathbb{C} \mid |z| = 1\} \subset \mathbb{C}$, $\mathbb{R}_+ = \{x \in \mathbb{R} \mid x > 0\}$, $\mathbb{Z}_m = \mathbb{Z}/m\mathbb{Z}$.

2.1. Description of elements in $G = \text{PSL}(2, \mathbb{R})$.

Elements of $\text{PSL}(2, \mathbb{R})$ can be classified with respect to the fixed point behavior of their action on \mathbb{H} . An element is called *hyperbolic* if it has two fixed points, which lie on the boundary $\partial\mathbb{H} = \mathbb{R} \cup \{\infty\}$ of \mathbb{H} . A hyperbolic element with fixed points α, β in \mathbb{R} is of the form

$$\tau_{\alpha, \beta}(\lambda) := \left[\frac{1}{(\alpha - \beta) \cdot \sqrt{\lambda}} \cdot \begin{pmatrix} \lambda\alpha - \beta & -(\lambda - 1)\alpha\beta \\ \lambda - 1 & \alpha - \lambda\beta \end{pmatrix} \right],$$

where $\lambda > 0$. A hyperbolic element with one fixed point in ∞ is of the form

$$\tau_{\infty, \beta}(\lambda) := \left[\frac{1}{\sqrt{\lambda}} \cdot \begin{pmatrix} \lambda & -(\lambda - 1)\beta \\ 0 & 1 \end{pmatrix} \right]$$

or

$$\tau_{\alpha, \infty}(\lambda) := \left[\frac{1}{\sqrt{\lambda}} \cdot \begin{pmatrix} 1 & (\lambda - 1)\alpha \\ 0 & \lambda \end{pmatrix} \right],$$

where α resp. β is the real fixed points and $\lambda > 0$. The parameter $\lambda > 0$ is called the *shift parameter*. The *axis* $\ell(g)$ of the element $g = \tau_{\alpha, \beta}(\lambda)$ is the geodesic between the fixed points α and β , oriented from β to α if $\lambda > 1$ and from α to β if $\lambda < 1$. The element $g = \tau_{\alpha, \beta}(\lambda)$ preserves the geodesic $\ell(g)$ and moves the

points on this geodesic in the direction of the orientation. We call a hyperbolic element $\tau_{\alpha,\beta}(\lambda)$ with $\lambda > 1$ *positive* if $\alpha < \beta$. The map $\lambda \mapsto \tau_{\alpha,\beta}(\lambda)$ defines a homomorphism $\mathbb{R}_+ \rightarrow G$ (with respect to the multiplicative structure on \mathbb{R}_+). We have

$$(\tau_{\alpha,\beta}(\lambda))^{-1} = \tau_{\alpha,\beta}(\lambda^{-1}) = \tau_{\beta,\alpha}(\lambda).$$

An element is called *parabolic* if it has one fixed point, which is on the boundary $\partial\mathbb{H}$. A parabolic element with real fixed point α is of the form

$$\pi_\alpha(\lambda) := \left[\begin{pmatrix} 1 - \lambda\alpha & \lambda\alpha^2 \\ -\lambda & 1 + \lambda\alpha \end{pmatrix} \right].$$

A parabolic element with fixed point ∞ is of the form

$$\pi_\infty(\lambda) := \left[\begin{pmatrix} 1 & \lambda \\ 0 & 1 \end{pmatrix} \right].$$

We call a parabolic element $\pi_\alpha(\lambda)$ *positive* if $\lambda > 0$. The map $\lambda \mapsto \pi_\alpha(\lambda)$ defines a homomorphism $\mathbb{R} \rightarrow G$. (with respect to the additive structure on \mathbb{R}). We have

$$(\pi_\alpha(\lambda))^{-1} = \pi_\alpha(-\lambda).$$

An element that is neither hyperbolic nor parabolic is called *elliptic*. It has one fixed point that is in \mathbb{H} . Given a base-point $x \in \mathbb{H}$ and a real number φ , let $\rho_x(\varphi) \in G$ denote the rotation through angle φ about the point x . Any elliptic element is of the form $\rho_x(\varphi)$, where x is the fixed point. Thus we obtain a 2π -periodic homomorphism $\rho_x : \mathbb{R} \rightarrow G$ (with respect to the additive structure on \mathbb{R}). We have

$$\rho_x(\varphi + 2\pi) = \rho_x(\varphi) \quad \text{and} \quad (\rho_x(\varphi))^{-1} = \rho_x(-\varphi).$$

For the fixed point $x = i \in \mathbb{H}$ we have

$$\rho_i(\varphi) = \left[\begin{pmatrix} \cos \frac{\varphi}{2} & -\sin \frac{\varphi}{2} \\ \sin \frac{\varphi}{2} & \cos \frac{\varphi}{2} \end{pmatrix} \right].$$

For a fixed point $x \in \mathbb{H} \setminus \{i\}$ we obtain $\rho_x(\varphi) = \tau \circ \rho_i(\varphi) \circ \tau^{-1}$, where τ is the hyperbolic element in G such that $\tau(i) = x$.

2.2. Coverings G_m of G .

As topological space $\text{PSL}(2, \mathbb{R})$ is homeomorphic to the open solid torus $\mathbb{S}^1 \times \mathbb{C}$. A homeomorphism $\text{PSL}(2, \mathbb{R}) \rightarrow \mathbb{S}^1 \times \mathbb{C}/\{\pm 1\}$ can be given explicitly, see the discussion before the proof of Lemma 2.4.

The fundamental group of the open solid torus G is infinite cyclic. Therefore, for each natural number m there is a unique connected m -fold covering

$$G_m = \tilde{G}/(m \cdot Z(\tilde{G}))$$

of G , where \tilde{G} is the universal covering of G and $Z(\tilde{G})$ is the centre of \tilde{G} . For $m = 2$ this is the group $G_2 = \text{SL}(2, \mathbb{R})$.

Here is another description of the covering groups G_m of $G = \text{PSL}(2, \mathbb{R})$, which fixes a group structure. Let $\text{Hol}(\mathbb{H}, \mathbb{C}^*)$ be the set of all holomorphic functions $\mathbb{H} \rightarrow \mathbb{C}^*$.

Proposition 2.1. *The m -fold covering group G_m of G can be described as*

$$\{(g, \delta) \in G \times \text{Hol}(\mathbb{H}, \mathbb{C}^*) \mid \delta^m(z) = g'(z) \text{ for all } z \in \mathbb{H}\}$$

with multiplication

$$(g_2, \delta_2) \cdot (g_1, \delta_1) = (g_2 \cdot g_1, (\delta_2 \circ g_1) \cdot \delta_1).$$

Proof. Let X be the subspace of $G \times \text{Hol}(\mathbb{H}, \mathbb{C}^*)$ in question. One can check that the space X is connected and that the map $X \rightarrow G$ given by $(\gamma, \delta) \mapsto \gamma$ is an m -fold covering of G . Hence the coverings $X \rightarrow G$ and $G_m \rightarrow G$ are isomorphic. One can check that the operation described above defines a group structure on X and that the covering map $X \rightarrow G$ is a homomorphism with respect to this group structure. ■

Remark. This description of G_m is inspired by the notion of automorphic differential forms of fractional degree, introduced by J. Milnor in [13]. For a more detailed discussion of this fact see [5], section 1.8.

Elements of \tilde{G} resp. G_m can also be classified with respect to the fixed point behavior of action on \mathbb{H} of their image in $G = \text{PSL}(2, \mathbb{R})$.

Definition 2.1. We say that an element of \tilde{G} resp. G_m is *hyperbolic*, *parabolic*, resp. *elliptic* if its image in G has this property.

2.3. One-Parameter-Subgroups of G and \tilde{G} .

The homomorphisms

$$\tau_{\alpha, \beta} : \mathbb{R}_+ \rightarrow G, \quad \pi_\alpha : \mathbb{R} \rightarrow G, \quad \text{resp.} \quad \rho_x : \mathbb{R} \rightarrow G$$

define one-parameter-subgroups in the group $G = \text{PSL}(2, \mathbb{R})$.

Each of the homomorphisms $\tau_{\alpha, \beta} : \mathbb{R}_+ \rightarrow G$, $\pi_\alpha : \mathbb{R} \rightarrow G$, resp. $\rho_x : \mathbb{R} \rightarrow G$ lifts to a unique homomorphism

$$t_{\alpha, \beta} : \mathbb{R}_+ \rightarrow \tilde{G}, \quad p_\alpha : \mathbb{R} \rightarrow \tilde{G} \quad \text{resp.} \quad r_x : \mathbb{R} \rightarrow \tilde{G}$$

into the universal covering group. The elements $t_{\alpha, \beta}(\lambda)$, $p_\alpha(\lambda)$, resp. $r_x(\xi)$ are hyperbolic, parabolic, resp. elliptic.

2.4. The Centre of the Group \tilde{G} .

Since $\rho_x(2\pi\ell) = \text{id}$ for $\ell \in \mathbb{Z}$, it follows that the lifted element $r_x(2\pi\ell)$ belongs to the centre $Z(\tilde{G})$ of \tilde{G} . Note that this element $r_x(2\pi\ell)$ depends continuously on x . But the centre of \tilde{G} is discrete, so this element must remain constant, thus $r_x(2\pi\ell)$ does not depend on x . The centre $Z(\tilde{G})$ of \tilde{G} is equal to the pre-image of the identity element under the projection $\tilde{G} \rightarrow G$, hence

$$Z(\tilde{G}) = \{r_x(2\pi\ell) \mid \ell \in \mathbb{Z}\}.$$

Let

$$u = r_x(2\pi)$$

for some (and hence for any) x in \mathbb{H} . The element u is one of the two generators of the centre of \tilde{G} , since any other element of the centre is of the form $r_x(2\pi\ell) = (r_x(2\pi))^\ell$.

2.5. Decomposition of the Subset of Hyperbolic and Parabolic Elements in \tilde{G} and G_m into Sheets.

Let Ξ be the subset of $G = \mathrm{PSL}(2, \mathbb{R})$ that consists of all hyperbolic and parabolic elements of G (including the identity element). The space G is homeomorphic to the open solid torus $\mathbb{S}^1 \times \mathbb{C}$. In [4] Jankins and Neumann give an explicit homeomorphism (see [4], Appendix) and describe the image of the subset Ξ under this homeomorphism (see [4], § 1, Figure 1). From this description it follows in particular that the subset Ξ is simply connected. The pre-image $\tilde{\Xi}$ of the subset Ξ in \tilde{G} consists of infinitely many connected components. Each connected component of the subset $\tilde{\Xi}$ contains one and only one pre-image of the identity element of G , i.e. one and only one element of the centre of \tilde{G} . The elements of the one-parameter-subgroups $t_{\alpha,\beta}(\lambda)$ resp. $p_\alpha(\lambda)$ are contained in the same connected component of the subset $\tilde{\Xi}$ as the identity element \tilde{e} of the group \tilde{G} .

Definition 2.2. If a hyperbolic or parabolic element of \tilde{G} is contained in the same connected component as the central element u^k , $k \in \mathbb{Z}$, we say that the element is *at the level k* and set the *level function* s on this element to be equal to k . Any hyperbolic resp. parabolic element in \tilde{G} is of the form $t_{\alpha,\beta}(\lambda) \cdot u^k$ resp. $p_\alpha(\lambda) \cdot u^k$. For elements written in this form we have

$$s(t_{\alpha,\beta}(\lambda) \cdot u^k) = k, \quad s(p_\alpha(\lambda) \cdot u^k) = k.$$

Definition 2.3. We define the *level function* s_m on the hyperbolic and parabolic elements of $G_m = \tilde{G}/(m \cdot Z(\tilde{G}))$ by

$$s_m(g \bmod (m \cdot Z(\tilde{G}))) = s(g) \bmod m \quad \text{for } g \in \tilde{G}.$$

We recall that $\mathbb{Z}_m = \mathbb{Z}/m\mathbb{Z}$. All equations involving s_m are to be understood as equations in \mathbb{Z}_m , i.e. equations modulo m .

2.6. Properties of the multiplication of hyperbolic and parabolic elements in G_m .

In this subsection we first study (Lemma 2.2 and 2.3) the behavior of the level functions s_m under inversion and conjugation. The main results of this subsection (Lemma 2.4, 2.6, and 2.7) are statements about the behavior of s_m under multiplication.

In this subsection let us denote by $[\cdot]$ the image of an element in \tilde{G} under the covering map $\tilde{G} \rightarrow G_m$.

Lemma 2.2. *The equation $s_m(A^{-1}) = -s_m(A)$ is satisfied for any hyperbolic or parabolic element A in G_m .*

Proof. The hyperbolic resp. parabolic element A is of the form $[t_{\alpha,\beta}(\lambda) \cdot u^k]$ resp. $[p_\alpha(\lambda) \cdot u^k]$. If $A = [t_{\alpha,\beta}(\lambda) \cdot u^k]$ then $A^{-1} = [t_{\alpha,\beta}(\lambda^{-1}) \cdot u^{-k}]$ and $s_m(A^{-1}) = -k = -s_m(A)$. If $A = [p_\alpha(\lambda) \cdot u^k]$ then $A^{-1} = [p_\alpha(-\lambda) \cdot u^{-k}]$ and $s_m(A^{-1}) = -k = -s_m(A)$. ■

Lemma 2.3. *For any hyperbolic or parabolic element A and any element B in G_m we have*

$$s_m(B \cdot A \cdot B^{-1}) = s_m(A).$$

Proof. The element B can be connected to the unit element in G_m via a path $\beta : I \rightarrow G_m$, where I is some closed interval. The path $\gamma : I \rightarrow G_m$ given by

$$\gamma(t) = \beta(t) \cdot A \cdot (\beta(t))^{-1}$$

connects the elements A and $B \cdot A \cdot B^{-1}$. We have

$$|\text{trace}(\gamma(t))| = |\text{trace}(\beta(t) \cdot A \cdot (\beta(t))^{-1})| = |\text{trace}(A)| \neq 0$$

for all $t \in I$ and hence s_m is constant along γ , in particular $s_m(B \cdot A \cdot B^{-1}) = s_m(A)$. (Here $|\text{trace } X|$ for an element X in G_m is defined as $|\text{trace } \bar{X}|$, where \bar{X} is the projection of X in G .) ■

Lemma 2.4. *For preimages A resp. B in G_m of the elements $\bar{A} = \tau_{\infty,0}(\lambda_1)$ resp. $\bar{B} = \tau_{\alpha,\beta}(\lambda_2)$ for some $\lambda_1, \lambda_2 > 1$ and $\alpha, \beta \in \mathbb{R} \setminus \{0\}$ the difference*

$$s_m(A \cdot B) - s_m(A) - s_m(B)$$

is equal to

- +1 if

$$0 < \frac{\lambda_1 + \lambda_2}{1 + \lambda_1 \lambda_2} \cdot \beta < \alpha < \beta,$$

- -1 if

$$\beta < \alpha \leq \frac{\lambda_1 + \lambda_2}{1 + \lambda_1 \lambda_2} \cdot \beta < 0,$$

- 0 otherwise.

One of the consequences of Lemma 2.4 is the following corollary:

Corollary 2.5. *If the axes of two hyperbolic elements A and B in G_m intersect, then*

$$s_m(A \cdot B) = s_m(A) + s_m(B).$$

This corollary can be shown in a more geometrical way:

Let ℓ_A resp. ℓ_B be the axes of A resp. B . Let x be the intersection point of ℓ_A and ℓ_B . Any hyperbolic transformation with the axis ℓ_A is a product of a rotation by π at some point $y \neq x$ on ℓ_A and a rotation by π at the point x . Similarly any hyperbolic transformation with the axis ℓ_B is a product of a rotation by π at the point x and a rotation by π at some point $z \neq x$ on ℓ_B . Hence the product of any hyperbolic transformation with the axis ℓ_A and any hyperbolic transformation with the axis ℓ_B is a product of a rotation by π at a point $y \neq x$ on ℓ_A and a rotation by π at a point $z \neq x$ on ℓ_B , i.e. it is a hyperbolic transformation with an axis going through the points y and z . Thus the product

of two hyperbolic elements with distinct but intersecting axes is always a hyperbolic element.

Assume without loss of generality that the elements A and B satisfy the conditions $s_m(A) = s_m(B) = 0$. We want to show that $s_m(AB) = 0$. Let us deform the elements A and B by decreasing their shift parameters, then their product tends to the identity element but remains hyperbolic, hence $s_m(AB)$ is equal to the value of s_m at the identity, i.e. $s_m(AB) = 0$.

However, we can not give a similarly illuminating geometrical proof for the other parts of Lemma 2.4 and will prove these cases by computation. To this end we will need the following definition:

The homeomorphism $\mathrm{PSL}(2, \mathbb{R}) \rightarrow \mathbb{S}^1 \times \mathbb{C}/\{\pm 1\}$ can be given explicitly as

$$H : \left[\begin{pmatrix} a & b \\ c & d \end{pmatrix} \right] \mapsto \left(\left(\frac{(a+d) + i(b-c)}{|(a+d) + i(b-c)|} \right)^2, \left[\frac{(a-d) + i(b+c)}{2} \right] \right).$$

Here we denote by $[A] = \left[\begin{pmatrix} a & b \\ c & d \end{pmatrix} \right] \in \mathrm{PSL}(2, \mathbb{R})$ the equivalence class of a matrix $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}(2, \mathbb{R})$, and by $[z] \in \mathbb{C}/\{\pm 1\}$ the equivalence class of $z \in \mathbb{C}$. The map $\mu : G \rightarrow \mathbb{S}^1$ defined as the composition of the homeomorphism H and the projection onto the factor \mathbb{S}^1 maps an element $[A] = \left[\begin{pmatrix} a & b \\ c & d \end{pmatrix} \right] \in G$ to a unit complex number $\mu([A]) = e^{i\psi}$ with

$$\tan \frac{\psi}{2} = \frac{b-c}{a+d}.$$

We shall refer to the number ψ as the *argument* of the element $[A]$. The map $\mu : G \rightarrow \mathbb{S}^1$ lifts to the unique map $\varphi : \tilde{G} \rightarrow \mathbb{R}$ of the universal covers such that the following diagram commutes

$$\begin{array}{ccc} \tilde{G} & \xrightarrow{\varphi} & \mathbb{R} \\ \downarrow & & \downarrow \\ G & \xrightarrow{\mu} & \mathbb{S}^1 \end{array}$$

and $\varphi(\tilde{e}) = 0$, where \tilde{e} is the identity element in \tilde{G} . Here the map $\mathbb{R} \rightarrow \mathbb{S}^1$ is the universal covering map given by $x \mapsto e^{ix}$. The map φ will help us to compute the level function. For hyperbolic and parabolic elements we have

$$s(g) = k \quad \text{for } g \in \tilde{G} \quad \text{if and only if } \varphi(g) \in (-\pi + 2\pi k, \pi + 2\pi k).$$

Proof. The expression $s_m(A \cdot B) - s_m(A) - s_m(B)$ is invariant under multiplication of A or B with the central element $[u]$, hence it is sufficient to prove the statement for elements A and B with $s_m(A) = s_m(B) = 0$, i.e. for $A = [t_{\infty,0}(\lambda_1)]$ and $B = [t_{\alpha,\beta}(\lambda_2)]$. Let us consider the path $\gamma : [0, 1] \rightarrow G$ from 1 to

$$\bar{A} \cdot \bar{B} = \tau_{\infty,0}(\lambda_1) \cdot \tau_{\alpha,\beta}(\lambda_2)$$

given by the suitably reparametrised product

$$\gamma(t) := \tau_{\infty,0}(\lambda_1(t)) \cdot \tau_{\alpha,\beta}(\lambda_2(t))$$

with $\lambda_j(t) = 1 + t(\lambda_j - 1)$ for $j = 1, 2$. Let $\tilde{\gamma} : [0, 1] \rightarrow G_m$ be the lift of this path covering with $\tilde{\gamma}(0) = e$. The path γ is homotopic to the path

$$\delta := (\tau_{\infty,0}|_{[1,\lambda_1]}) * (\tau_{\infty,0}(\lambda_1) \cdot \tau_{\alpha,\beta}|_{[1,\lambda_2]}),$$

where $*$ means to go along the first path and then along the second path. It is clear that

$$\tilde{\delta} := ([t_{\infty,0}]|_{[1,\lambda_1]}) * ([t_{\infty,0}(\lambda_1)] \cdot [t_{\alpha,\beta}]|_{[1,\lambda_2]})$$

is the lift of the path δ with the starting point e . The end point of the lifted path $\tilde{\delta}$ is $[t_{\infty,0}(\lambda_1) \cdot t_{\alpha,\beta}(\lambda_2)]$. Since the path γ is homotopic to δ , the lift $\tilde{\gamma}$ has the same end point as $\tilde{\delta}$, hence

$$\tilde{\gamma}(1) = [t_{\infty,0}(\lambda_1) \cdot t_{\alpha,\beta}(\lambda_2)] = A \cdot B.$$

So we have to compute

$$s_m(A \cdot B) - s_m(A) - s_m(B) = s_m(\tilde{\gamma}(1)).$$

On the other hand we have

$$\begin{aligned} \gamma(t) &= \tau_{\infty,0}(\lambda_1(t)) \cdot \tau_{\alpha,\beta}(\lambda_2(t)) \\ &= \left[\frac{1}{(\alpha - \beta) \cdot \sqrt{\lambda_1(t)\lambda_2(t)}} \cdot \begin{pmatrix} \lambda_1(t)(\lambda_2(t)\alpha - \beta) & -\lambda_1(t)(\lambda_2(t) - 1)\alpha\beta \\ \lambda_2(t) - 1 & \alpha - \lambda_2(t)\beta \end{pmatrix} \right]. \end{aligned}$$

Let $\Phi(t) = \varphi(\tilde{\gamma}(t))$. We obtain

$$\tan \frac{\Phi(t)}{2} = -\frac{(\lambda_1(t)\alpha\beta + 1)(\lambda_2(t) - 1)}{(\lambda_1(t)\lambda_2(t) + 1)\alpha - (\lambda_1(t) + \lambda_2(t))\beta}.$$

We observe that $\Phi(0) = 0$. The denominator of this fraction is

$$\begin{aligned} f(t) &:= (\lambda_1(t)\lambda_2(t) + 1)\alpha - (\lambda_1(t) + \lambda_2(t))\beta \\ &= (\lambda_1(t) + \lambda_2(t))(\alpha - \beta) + (\lambda_1(t) - 1)(\lambda_2(t) - 1)\alpha. \end{aligned}$$

Since $\lambda_1(t) + \lambda_2(t) > 0$ and $(\lambda_1(t) - 1)(\lambda_2(t) - 1) \geq 0$, if α and $\alpha - \beta$ are both positive or both negative, i.e. in the cases $\alpha < \beta < 0$, $\alpha < 0 < \beta$, $\beta < 0 < \alpha$ and $0 < \beta < \alpha$, we have $f(t) \neq 0$ for $t \in [0, 1]$. This implies $\Phi(1) \in (-\pi, \pi)$ and hence

$$s_m(A \cdot B) - s_m(A) - s_m(B) = s_m(\tilde{\gamma}(1)) = 0.$$

In the cases $0 < \alpha < \beta$ resp. $\beta < \alpha < 0$ we have to look carefully at the argument $\Phi(t)$. The argument $\Phi(t)$ satisfies the equation

$$\tan \frac{\Phi(t)}{2} = \frac{-(\lambda_1(t)\alpha\beta + 1)(\lambda_2(t) - 1)}{f(t)}$$

where

$$\begin{aligned} f(t) &= (\lambda_1(t)\lambda_2(t) + 1)\alpha - (\lambda_1(t) + \lambda_2(t))\beta \\ &= \alpha(\lambda_1 - 1)(\lambda_2 - 1) \cdot t^2 + (\alpha - \beta)((\lambda_1 - 1) + (\lambda_2 - 1)) \cdot t + 2(\alpha - \beta) \end{aligned}$$

is a quadratic function. Since $\alpha \cdot \beta > 0$, $\lambda_1(t) > 0$ and $\lambda_2(t) \geq 1$, the sign of $\tan(\Phi(t)/2)$ is opposite to the sign of $f(t)$.

Let us assume that $0 < \alpha < \beta$. The coefficient $\alpha(\lambda_1 - 1)(\lambda_2 - 1)$ by t^2 in $f(t)$ is positive, hence the function f is concave. We observe that

$$\begin{aligned} f(0) &= 2(\alpha - \beta) < 0, \\ f(1) &= (\lambda_1\lambda_2 + 1)\alpha - (\lambda_1 + \lambda_2)\beta. \end{aligned}$$

There are two cases, $f(1) \leq 0$ and $f(1) > 0$.

Let us assume that $0 < \alpha < \beta$ and $f(1) \leq 0$. Then $f(0) < 0$, $f(1) \leq 0$ and f concave implies $f(t) < 0$ for $t \in [0, 1)$, hence $\tan(\Phi(t)/2) > 0$ for $t \in (0, 1)$. This implies $\Phi(t) \in [0, \pi]$ and hence

$$s_m(A \cdot B) - s_m(A) - s_m(B) = s_m(\tilde{\gamma}(1)) = 0.$$

Let us assume that $0 < \alpha < \beta$ and $f(1) > 0$, which is equivalent to

$$0 < \frac{\lambda_1 + \lambda_2}{1 + \lambda_1\lambda_2} \cdot \beta < \alpha < \beta.$$

Then $f(0) < 0$, $f(1) > 0$ and f quadratic implies that there is $t_0 \in (0, 1)$ such that $f(t_0) = 0$, $f(t) < 0$ for $t \in [0, t_0)$, and $f(t) > 0$ for $t \in (t_0, 1]$. Hence $\tan(\Phi(t)/2) > 0$ for $t \in (0, t_0)$ and $\tan(\Phi(t)/2) < 0$ for $t \in (t_0, 1]$. This implies $\Phi(1) \in (\pi, 2\pi]$ and hence

$$s_m(A \cdot B) - s_m(A) - s_m(B) = s_m(\tilde{\gamma}(1)) = 1.$$

Let us assume that $\beta < \alpha < 0$. The coefficient $\alpha(\lambda_1 - 1)(\lambda_2 - 1)$ by t^2 in $f(t)$ is negative, hence the function f is convex. We observe

$$\begin{aligned} f(0) &= 2(\alpha - \beta) > 0, \\ f(1) &= (\lambda_1\lambda_2 + 1)\alpha - (\lambda_1 + \lambda_2)\beta. \end{aligned}$$

There are two cases, $f(1) > 0$ and $f(1) \leq 0$.

Let us assume that $\beta < \alpha < 0$ and $f(1) > 0$. Then $f(0) > 0$, $f(1) > 0$ and f convex implies $f(t) \neq 0$ for $t \in [0, 1]$, hence $s_m(A \cdot B) - s_m(A) - s_m(B) = 0$ as before.

Let us assume that $\beta < \alpha < 0$ and $f(1) \leq 0$, which is equivalent to

$$\beta < \alpha \leq \frac{\lambda_1 + \lambda_2}{1 + \lambda_1\lambda_2} \cdot \beta < 0.$$

Then $f(0) > 0$, $f(1) \leq 0$ and f quadratic implies that there is $t_0 \in (0, 1]$ such that $f(t_0) = 0$, $f(t) > 0$ for $t \in [0, t_0)$, and $f(t) < 0$ for $t \in (t_0, 1]$. Hence $\tan(\Phi(t)/2) < 0$ for $t \in (0, t_0)$ and $\tan(\Phi(t)/2) > 0$ for $t \in (t_0, 1]$. This implies $\Phi(1) \in [-2\pi, -\pi]$ and hence

$$s_m(A \cdot B) - s_m(A) - s_m(B) = s_m(\tilde{\gamma}(1)) = -1. \quad \blacksquare$$

The results similar to Lemma 2.4 hold also for products of hyperbolic and parabolic elements as well as for products of parabolic elements:

Lemma 2.6. *For preimages A resp. B in G_m of the elements $\bar{A} = \tau_{\infty,0}(\lambda_1)$ resp. $\bar{B} = \pi_\alpha(\lambda_2)$ for some $\lambda_1 > 1$, $\lambda_2 > 0$ and $\alpha > 0$ the difference*

$$s_m(A \cdot B) - s_m(A) - s_m(B)$$

is equal

- to 0 if

$$\lambda_2 \alpha \leq \frac{\lambda_1 + 1}{\lambda_1 - 1},$$

- and to 1 otherwise.

Lemma 2.7. *For preimages A resp. B in G_m of the elements $\bar{A} = \pi_\infty(\lambda_1)$ resp. $\bar{B} = \pi_\alpha(\lambda_2)$ for some $\lambda_1, \lambda_2, \alpha > 0$ the difference*

$$s_m(A \cdot B) - s_m(A) - s_m(B)$$

is equal

- to 0 if $\lambda_1 \lambda_2 \leq 2$,
- and to 1 otherwise.

We omit the proofs of Lemmata 2.6 and 2.7, which are along the lines of the proof of Lemma 2.4.

3. Higher spin structures and lifts of Fuchsian groups

3.1. Higher spin structures.

Let $E \rightarrow P$ be complex line bundle over a hyperbolic Riemann surface P . Let Γ be a torsionfree Fuchsian group such that $P = \mathbb{H}/\Gamma$. Let $L \rightarrow \mathbb{H}$ be the induced complex line bundle over \mathbb{H} . Let $L \simeq \mathbb{H} \times \mathbb{C}$ be a trivialization of the bundle L . With respect to this trivialization the action of Γ on L is given by

$$g \cdot (z, t) = (g(z), \delta(g, z) \cdot t),$$

where $\delta : \Gamma \times \mathbb{H} \rightarrow \mathbb{C}^*$ is a map such that the function $\delta_g = \delta|_{\{g\} \times \mathbb{H}}$ is holomorphic for any $g \in \Gamma$ and for any $g_1, g_2 \in \Gamma$ we have

$$\delta_{g_2 \cdot g_1} = (\delta_{g_2} \circ g_1) \cdot \delta_{g_1}.$$

The map δ is called the *transition map* of the bundle $E \rightarrow P$ with respect to the given trivialization.

In particular, if E is the cotangent bundle of the surface P , then the transition map can be chosen so that $\delta_g = (g')^{-1}$. If E is the tangent bundle of the surface P , then the transition map can be chosen so that $\delta_g = g'$. Let

$E_1 \rightarrow P$, $E_2 \rightarrow P$ be two complex line bundles over a Riemann surface P , and let δ_1 resp. δ_2 be their transition maps, then $\delta_1 \cdot \delta_2$ is a transition map of the bundle $E_1 \otimes E_2 \rightarrow P$. In particular, if δ is the transition map of the bundle $E \rightarrow P$, then δ^m is a transition map of the bundle $E^m = E \otimes \cdots \otimes E \rightarrow P$ (with respect to the induced trivialization).

An *m-spin structure* on a Riemann surface P is a transition map δ of a complex line bundle $E \rightarrow P$ that satisfies the condition $\delta_g^m = (g')^{-1}$, i.e. the induced transition map δ^m of the bundle $E^m \rightarrow P$ coincides with the transition map of the cotangent bundle of P .

Remark. An *m-co-spin structure* on a Riemann surface P is a transition map δ of a complex line bundle $E \rightarrow P$ that satisfies the condition $\delta_g^m = g'$, i.e. the induced transition map δ^m of the bundle $E^m \rightarrow P$ coincides with the transition map of the tangent bundle of P . There is a one-to-one correspondence between *m-spin* and *m-co-spin* structures on a Riemann surface given by taking E to E^{-1} resp., in terms of transition maps, by taking δ to δ^{-1} . In the following we consider the *m-spin* structures.

Remark. A complex line bundle $E \rightarrow P$ is said to be *m-spin* if the bundle $E^m \rightarrow P$ is isomorphic to the cotangent bundle of P . For a compact Riemann surface P there is a 1-1-correspondence between *m-spin* structures on P and *m-spin* bundles over P .

Definition 3.1. A *lift* of the Fuchsian group Γ into G_m is a subgroup Γ^* of G_m such that the restriction of the covering map $G_m \rightarrow G$ to Γ^* is an isomorphism between Γ^* and Γ .

Proposition 3.1. *There is a 1-1-correspondence between m-spin structures on the Riemann surface $P = \mathbb{H}/\Gamma$ and lifts of Γ into G_m .*

Proof. We use the description in Proposition 2.1 of the covering G_m as the group

$$\{(g, \delta) \in G \times \text{Hol}(\mathbb{H}, \mathbb{C}^*) \mid \delta^m(z) = g'(z) \text{ for all } z \in \mathbb{H}\}$$

with multiplication

$$(g_2, \delta_2) \cdot (g_1, \delta_1) = (g_2 \cdot g_1, (\delta_2 \circ g_1) \cdot \delta_1).$$

From this description of G_m we see that choosing a lift of Γ into G_m amounts to choosing for each $g \in \Gamma$ a holomorphic function $\delta_g : \mathbb{H} \rightarrow \mathbb{C}^*$ that satisfies the condition $\delta_g^m = g'$ so that the family $\{\delta_g\}_{g \in \Gamma}$ satisfies the condition

$$\delta_{g_2 \cdot g_1} = (\delta_{g_2} \circ g_1) \cdot \delta_{g_1} \quad \text{for any } g_1, g_2 \in \Gamma.$$

On the other hand as we explained in this section an *m-spin* structure on the Riemann surface $P = \mathbb{H}/\Gamma$ is described by a family $\{\delta_g\}_{g \in \Gamma}$ that satisfies the same conditions

$$\delta_g^m = g' \quad \text{for any } g \in \Gamma$$

and

$$\delta_{g_2 \cdot g_1} = (\delta_{g_2} \circ g_1) \cdot \delta_{g_1} \quad \text{for any } g_1, g_2 \in \Gamma.$$

Hence there is a 1-1-correspondence between *m-spin* structures on the Riemann surface $P = \mathbb{H}/\Gamma$ and lifts of Γ into G_m . ■

Figure 1: Axes of a sequential set of type $(0, 3, 0)$

3.2. Finitely generated Fuchsian groups.

In this section we are going to describe finitely generated Fuchsian groups using standard sets of generators. Definition 3.3 corresponds to the case of the fundamental group of a sphere with punctures and holes with the total number of punctures and holes equal to three. Definition 3.4 corresponds to the case of the fundamental group of a sphere with an arbitrary number of punctures and holes. Finally in Definition 3.5 we describe the fundamental group of a surface (of possibly higher genus g) with punctures and holes. Hereby we use the observation that if we think of the surface as a sphere with g handles (and punctures and holes) and cut all handles along their waist curves then we obtain a sphere with the same number of punctures and the number of holes increased by $2g$.

Definition 3.2. For two elements C_1 and C_2 in G with finite fixed points in \mathbb{R} we say that $C_1 < C_2$ if all fixed point of C_1 are smaller than any fixed point of C_2 .

Definition 3.3. A *sequential set of type* $(0, l_h, l_p)$ with $l_h + l_p = 3$ is a triple of elements (C_1, C_2, C_3) in G such that the elements C_i for $1 \leq i \leq l_h$ are hyperbolic, the elements C_i for $l_h < i \leq 3$ are parabolic, their product is

$$C_1 \cdot C_2 \cdot C_3 = 1,$$

and for some element $A \in G$ the elements $\{\tilde{C}_i = AC_iA^{-1}\}_{i=1,2,3}$ are positive, have finite fixed points and satisfy $\tilde{C}_1 < \tilde{C}_2 < \tilde{C}_3$. (Figure 1 illustrates the position of the axes of the elements \tilde{C}_i for a sequential set of type $(0, 3, 0)$, i.e. when all elements are hyperbolic.)

Definition 3.4. A *sequential set of type* $(0, l_h, l_p)$ is an n -tuple of elements

$$(C_1, \dots, C_n)$$

with $n = l_h + l_p$ in G such that the elements C_1, \dots, C_{l_h} are hyperbolic, the elements C_{l_h+1}, \dots, C_n are parabolic, and for any $j \in \{2, \dots, n - 1\}$ the triple

$$(C_1 \cdots C_{j-1}, C_j, C_{j+1} \cdots C_n)$$

is a sequential set (of type $(0, 3, 0)$, $(0, 2, 1)$, $(0, 1, 2)$ or $(0, 0, 3)$).

Definition 3.5. A *sequential set of type* (g, l_h, l_p) is a $(2g + l_h + l_p)$ -tuple of elements

$$(A_1, \dots, A_g, B_1, \dots, B_g, C_{g+1}, \dots, C_{g+l_h+l_p})$$

in G such that the elements $A_1, \dots, A_g, B_1, \dots, B_g$ and $C_{g+1}, \dots, C_{g+l_h}$ are hyperbolic, the elements $C_{g+l_h+1}, \dots, C_{g+l_h+l_p}$ are parabolic, and the tuple

$$(A_1, B_1A_1^{-1}B_1^{-1}, \dots, A_g, B_gA_g^{-1}B_g^{-1}, C_{g+1}, \dots, C_{g+l_h+l_p})$$

is a sequential set of type $(0, 2g + l_h, l_p)$.

Figure 2: Standard basis

Definition 3.6. We call a Riemann surface of genus g with l_h holes and l_p punctures a *Riemann surface of type* (g, l_h, l_p) .

Definition 3.7. We define the product ab of two contours a and b in $\pi_1(P, p)$ as the contour given by the path of b followed by the path of a . A *standard basis* of a fundamental group $\pi_1(P, p)$ of a surface P of type (g, l_h, l_p) is a set of generators

$$\{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\}$$

with a single defining relation

$$\prod_{i=1}^g [a_i, b_i] \prod_{i=g+1}^n c_i = 1$$

and represented by a set of simple contours

$$\{\tilde{a}_i, \tilde{b}_i \ (i = 1, \dots, g), \tilde{c}_i \ (i = g + 1, \dots, n)\}$$

with the following properties:

- 1) the contour \tilde{c}_i encloses a hole in P for $i = g + 1, \dots, g + l_h$ and a puncture for $i = g + l_h + 1, \dots, n$,
- 2) $\tilde{a}_i \cap \tilde{b}_j = \tilde{a}_i \cap \tilde{c}_j = \tilde{b}_i \cap \tilde{c}_j = \tilde{c}_i \cap \tilde{c}_j = \{p\}$.
- 3) in a neighbourhood of the point p , the contours are placed as is shown in Figure 2.

The relation between sequential sets and Fuchsian groups is exploited in [6] (Chapter 1, Theorem 1.1, Lemma 2.1, Theorem 2.1). We recall here the results:

Theorem 3.2. A sequential set V of type (g, l_h, l_p) generates a Fuchsian group Γ such that the surface $P = \mathbb{H}/\Gamma$ is of type (g, l_h, l_p) . The isomorphism $\Phi : \Gamma \rightarrow \pi_1(P, p)$, induced by the natural projection $\Psi : \mathbb{H} \rightarrow P$, maps the sequential set V to a standard basis of $\pi_1(P, p)$.

Theorem 3.3. Let Γ be a Fuchsian group such that the surface $P = \mathbb{H}/\Gamma$ is of type (g, l_h, l_p) . Let p be a point in P . Let $\Psi : \mathbb{H} \rightarrow P$ be the natural projection. Choose $q \in \Psi^{-1}(p)$ and let $\Phi : \Gamma \rightarrow \pi_1(P, p)$ be the induced isomorphism. Let

$$v = \{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\}$$

be a standard basis of $\pi_1(P, p)$. In this case,

$$\begin{aligned} V = \Phi^{-1}(v) &= \{\Phi^{-1}(a_i), \Phi^{-1}(b_i) \ (i = 1, \dots, g), \Phi^{-1}(c_i) \ (i = g + 1, \dots, n)\} \\ &= \{A_i, B_i \ (i = 1, \dots, g), C_i \ (i = g + 1, \dots, n)\} \end{aligned}$$

is a sequential set of type (g, l_h, l_p) .

Now we recall the classification of free Fuchsian groups of rank 2 (see [6], Chapter 1, Lemma 3.2, 3.3, 3.4):

Lemma 3.4. *The set $(C_1 = \tau_{\infty,0}(\lambda_1), C_2 = \tau_{\alpha,\beta}(\lambda_2), C_3)$ with $\lambda_1, \lambda_2 > 1$ is a sequential set of type $(0, 3, 0)$ or $(0, 2, 1)$ if and only if*

$$C_3 = (C_1 \cdot C_2)^{-1}$$

and

$$0 < \left(\frac{\sqrt{\lambda_1} + \sqrt{\lambda_2}}{1 + \sqrt{\lambda_1 \lambda_2}} \right)^2 \beta \leq \alpha < \beta < \infty.$$

Then the set (C_1, C_2, C_3) is of type $(0, 2, 1)$, i.e. the element C_3 is parabolic, if and only if

$$\alpha = \left(\frac{\sqrt{\lambda_1} + \sqrt{\lambda_2}}{1 + \sqrt{\lambda_1 \lambda_2}} \right)^2 \beta.$$

Lemma 3.5. *The set $(C_1 = \tau_{\infty,0}(\lambda_1), C_2 = \pi_\alpha(\lambda_2), C_3)$ with $\lambda_1 > 1, \lambda_2 > 0$ is a sequential set of type $(0, 2, 1)$ or $(0, 1, 2)$ if and only if*

$$C_3 = (C_1 \cdot C_2)^{-1}$$

and

$$\lambda_2 \alpha \geq \frac{\sqrt{\lambda_1} + 1}{\sqrt{\lambda_1} - 1}.$$

Then the set (C_1, C_2, C_3) is of type $(0, 1, 2)$, i.e. the element C_3 is parabolic, if and only if the last inequality is an equality.

Lemma 3.6. *If the set (A_1, B_1, C_1) is a sequential set of type $(1, 1, 0)$ then the axes of the hyperbolic elements A_1 and B_1 intersect.*

3.3. Lifting sets of generators of Fuchsian groups.

In this subsection let us denote by $[\cdot]$ the image of an element in \tilde{G} under the covering map $\tilde{G} \rightarrow G_m$.

Lemma 3.7. *Let Γ be a Fuchsian group of type (g, l_h, l_p) generated by the sequential set*

$$\begin{aligned} \bar{V} &= \{\bar{A}_i, \bar{B}_i \ (i = 1, \dots, g), \bar{C}_i \ (i = g + 1, \dots, n)\} \\ &= \{\bar{D}_j \ (j = 1, \dots, n + g)\}. \end{aligned}$$

Let

$$\begin{aligned} V &= \{A_i, B_i \ (i = 1, \dots, g), C_i \ (i = g + 1, \dots, n)\} \\ &= \{D_j \ (j = 1, \dots, n + g)\} \end{aligned}$$

be a set of the lifts of the elements of the sequential set \bar{V} into G_m , i.e. the image of D_j in G is \bar{D}_j . Then the subgroup Γ^* of G_m generated by V is a lift of Γ into G_m if and only if

$$\prod_{i=1}^g [A_i, B_i] \cdot \prod_{i=g+1}^n C_i = e.$$

Proof. For any choice of the set of lifts V the restriction of the covering map $G_m \rightarrow G$ to the group Γ^* generated by V is a homomorphism with image Γ . There is only one relation

$$\prod_{i=1}^g [\bar{A}_i, \bar{B}_i] \cdot \prod_{i=g+1}^n \bar{C}_i = e$$

in Γ , hence the equality

$$\prod_{i=1}^g [A_i, B_i] \cdot \prod_{i=g+1}^n C_i = e$$

ensures injectivity of this homomorphism. ■

Lemma 3.8. *Let (C_1, C_2, C_3) be a triple of elements in G_m such that their images $(\bar{C}_1, \bar{C}_2, \bar{C}_3)$ in G form a sequential set of type $(0, l_h, l_p)$ with $l_h + l_p = 3$. Then $C_1 \cdot C_2 \cdot C_3 = e$ if and only if*

$$s_m(C_1) + s_m(C_2) + s_m(C_3) = -1.$$

Moreover

$$s_m(C_1 \cdot C_2) = s_m(C_1) + s_m(C_2) + 1.$$

Proof. We first prove $s_m(C_1 \cdot C_2) = s_m(C_1) + s_m(C_2) + 1$ separately for sequential sets of types $(0, 3, 0)$ and $(0, 2, 1)$ using Lemma 2.4, for sequential sets of types $(0, 1, 2)$ and $(0, 2, 1)$ using Lemma 2.6, and for sequential sets of type $(0, 0, 3)$ using Lemma 2.7.

- We first assume that the elements C_1 and C_2 are hyperbolic. Up to conjugation we can assume that $\bar{C}_1 = \tau_{\infty, 0}(\lambda_1)$ and $\bar{C}_2 = \tau_{\alpha, \beta}(\lambda_2)$ for some $\lambda_1, \lambda_2 > 1$ and $\alpha, \beta \in \mathbb{R} \setminus \{0\}$. Lemma 3.4 implies that $\alpha, \beta > 0$ and

$$1 > \frac{\alpha}{\beta} > \left(\frac{\sqrt{\lambda_1} + \sqrt{\lambda_2}}{1 + \sqrt{\lambda_1 \lambda_2}} \right)^2 = \frac{\lambda_1 + \lambda_2 + 2\sqrt{\lambda_1 \lambda_2}}{1 + \lambda_1 \lambda_2 + 2\sqrt{\lambda_1 \lambda_2}} > \frac{\lambda_1 + \lambda_2}{1 + \lambda_1 \lambda_2}.$$

According to Lemma 2.4 the inequalities $\alpha \cdot \beta > 0$ and

$$\frac{\lambda_1 + \lambda_2}{1 + \lambda_1 \lambda_2} \cdot \beta < \alpha < \beta$$

imply

$$s_m(C_1 \cdot C_2) = s_m(C_1) + s_m(C_2) + 1.$$

- We now assume that the element C_1 is hyperbolic and the element C_2 is parabolic. Up to conjugation we can assume that $\bar{C}_1 = \tau_{\infty,0}(\lambda_1)$ and $\bar{C}_2 = \pi_\alpha(\lambda_2)$ for some $\lambda_1 > 1$, $\lambda_2 > 0$, and $\alpha > 0$. Lemma 3.5 implies that

$$\lambda_2\alpha \geq \frac{\sqrt{\lambda_1} + 1}{\sqrt{\lambda_1} - 1} = \frac{(\sqrt{\lambda_1} + 1)^2}{(\sqrt{\lambda_1} + 1) \cdot (\sqrt{\lambda_1} - 1)} = \frac{\lambda_1 + 1 + 2\sqrt{\lambda_1}}{\lambda_1 - 1} > \frac{\lambda_1 + 1}{\lambda_1 - 1}.$$

According to Lemma 2.6 the inequalities $\alpha > 0$ and

$$\lambda_2\alpha > \frac{\lambda_1 + 1}{\lambda_1 - 1}$$

imply

$$s_m(C_1 \cdot C_2) = s_m(C_1) + s_m(C_2) + 1.$$

- We now assume that the elements C_1 and C_2 are parabolic. Up to conjugation we can assume that

$$\bar{C}_1 = \pi_\infty(1) = \left[\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \right] \quad \text{and} \quad \bar{C}_2 = \pi_1(4) = \left[\begin{pmatrix} -3 & 4 \\ -4 & 5 \end{pmatrix} \right].$$

Then according to Lemma 2.7

$$s_m(C_1 \cdot C_2) = s_m(C_1) + s_m(C_2) + 1.$$

- In all three cases we proved that $s_m(C_1 \cdot C_2) = s_m(C_1) + s_m(C_2) + 1$. For the inverse element this implies

$$s_m((C_1 \cdot C_2)^{-1}) = -s_m(C_1 \cdot C_2) = -(s_m(C_1) + s_m(C_2) + 1).$$

The image of the element $C_1 \cdot C_2 \cdot C_3$ is $\bar{C}_1 \cdot \bar{C}_2 \cdot \bar{C}_3 = 1$, hence $C_1 \cdot C_2 \cdot C_3 = [u]^l$ for some $l \in \mathbb{Z}$. This implies

$$s_m(C_3) = s_m((C_1 \cdot C_2)^{-1} \cdot u^l) = l - (s_m(C_1) + s_m(C_2) + 1),$$

hence we obtain that $C_1 \cdot C_2 \cdot C_3 = e$ if and only if $l = 0$, i.e. if and only if

$$s_m(C_1) + s_m(C_2) + s_m(C_3) = -1. \quad \blacksquare$$

Lemma 3.9. *Let (A_1, B_1, C_1) be a triple of elements in G_m such that their images $(\bar{A}_1, \bar{B}_1, \bar{C}_1)$ in G form a sequential set of type $(1, 1, 0)$. Then*

$$[A_1, B_1] \cdot C_1 = e$$

if and only if

$$s_m(C_1) = -1.$$

Moreover,

$$s_m(A_1 \cdot B_1) = s_m(A_1) + s_m(B_1).$$

Proof. Lemma 3.6 implies that the axes of the hyperbolic elements A_1 and B_1 intersect. According to Corollary 2.5 this implies

$$s_m(A_1 \cdot B_1) = s_m(A_1) + s_m(B_1).$$

The triple $(\bar{A}_1, \bar{B}_1, \bar{C}_1)$ is a sequential set of type $(1, 1, 0)$. By the definition of sequential sets the triple $(\bar{A}_1, \bar{B}_1 \bar{A}_1^{-1} \bar{B}_1^{-1}, \bar{C}_1)$ is a sequential set of type $(0, 3, 0)$. According to Lemma 3.8 we have

$$[A_1, B_1] \cdot C_1 = A_1 \cdot (B_1 A_1^{-1} B_1^{-1}) \cdot C_1 = e$$

if and only if

$$s_m(A_1) + s_m(B_1 A_1^{-1} B_1^{-1}) + s_m(C_1) = -1.$$

Since by Lemma 2.3

$$s_m(B_1 A_1^{-1} B_1^{-1}) = s_m(A_1^{-1}) = -s_m(A_1),$$

the last condition is equivalent to

$$s_m(C_1) = -1. \quad \blacksquare$$

Lemma 3.10. *Let*

$$V = \{A_i, B_i \ (i = 1, \dots, g), C_i \ (i = g + 1, \dots, n)\}$$

be a tuple of elements in G_m such that the image

$$\bar{V} = \{\bar{A}_i, \bar{B}_i \ (i = 1, \dots, g), \bar{C}_i \ (i = g + 1, \dots, n)\}$$

in G form a sequential set. Then we have

$$\prod_{i=1}^g [A_i, B_i] \cdot \prod_{i=g+1}^n C_i = e$$

if and only if

$$\sum_{i=g+1}^n s_m(C_i) = (2 - 2g) - (n - g).$$

(In the case $n = g$ this means $2 - 2g = 0 \pmod{m}$.)

Proof. We discuss the case $g = 0$ first, and then we reduce the general case to the case $g = 0$.

- Let $g = 0$. We prove that the statement is true for lifts of sequential sets of type $(0, l_h, l_p)$ by induction on $l_h + l_p$. The case $l_h + l_p = 3$ is covered by Lemma 3.8. Assume that the statement is true for $l_h + l_p \leq n - 1$ and consider the case $l_h + l_p = n$. By the definition of sequential sets the set $(\bar{C}_1 \cdot \bar{C}_2, \bar{C}_3, \dots, \bar{C}_n)$ is a sequential set. Hence by our assumption $(C_1 \cdot C_2) \cdot C_3 \cdots C_n = e$ if and only if

$$s_m(C_1 \cdot C_2) + s_m(C_3) + \cdots + s_m(C_n) = 2 - (n - 1) = (2 - n) + 1.$$

Moreover, by the definition of sequential sets the set $(\bar{C}_1, \bar{C}_2, \bar{C}_3 \cdots \bar{C}_n)$ is a sequential set too, hence by Lemma 3.8 we have

$$s_m(C_1 \cdot C_2) = s_m(C_1) + s_m(C_2) + 1.$$

The last two equations imply that

$$C_1 \cdots C_n = e$$

if and only if

$$s_m(C_1) + \cdots + s_m(C_n) = 2 - n.$$

- We now consider the general case. By the definition of sequential sets the set

$$(\bar{A}_1, \bar{B}_1 \bar{A}_1^{-1} \bar{B}_1^{-1}, \dots, \bar{A}_g, \bar{B}_g \bar{A}_g^{-1} \bar{B}_g^{-1}, \bar{C}_1, \dots, \bar{C}_n)$$

is a sequential set of type $(0, 2g + l_h, l_p)$, hence

$$\prod_{i=1}^g [A_i, B_i] \cdot \prod_{i=g+1}^n C_i = \prod_{i=1}^g (A_i \cdot B_i A_i^{-1} B_i^{-1}) \cdot \prod_{i=g+1}^n C_i = e$$

if and only if

$$\begin{aligned} \sum_{i=1}^g (s_m(A_i) + s_m(B_i A_i^{-1} B_i^{-1})) + \sum_{i=g+1}^n s_m(C_i) &= 2 - (n + g) \\ &= (2 - 2g) - (n - g). \end{aligned}$$

From Lemma 2.3 we obtain that

$$s_m(B_i A_i^{-1} B_i^{-1}) = s_m(A_i^{-1}) = -s_m(A_i),$$

and hence

$$s_m(A_i) + s_m(B_i A_i^{-1} B_i^{-1}) = 0. \quad \blacksquare$$

4. Higher Arf functions

Let Γ be a Fuchsian group and $P = \mathbb{H}/\Gamma$ of type (g, l_h, l_p) with $l_h + l_p = n - g$. Let $p \in P$. Let $\Psi : \mathbb{H} \rightarrow P$ be the natural projection. Choose $q \in \Psi^{-1}(p)$ and let $\Phi : \Gamma \rightarrow \pi_1(P, p)$ be the induced isomorphism.

4.1. Definition of higher Arf functions.

Let Γ^* be a lift of Γ in G_m .

Definition 4.1. Let us consider a function $\hat{\sigma}_{\Gamma^*} : \pi_1(P, p) \rightarrow \mathbb{Z}_m$ such that the following diagram commutes

$$\begin{array}{ccc} \Gamma & \xrightarrow{\cong} & \Gamma^* \\ \Phi \downarrow & & \downarrow s_m|_{\Gamma^*} \\ \pi_1(P, p) & \xrightarrow{\hat{\sigma}_{\Gamma^*}} & \mathbb{Z}_m \end{array}$$

Figure 3: $\hat{\sigma}(ab) = \hat{\sigma}(a) + \hat{\sigma}(b) + 1$ Figure 4: $\hat{\sigma}(ab) = \hat{\sigma}(a) + \hat{\sigma}(b) - 1$

Lemma 4.1. *Let α , β , and γ be simple contours in P intersecting pairwise in exactly one point p . Let a , b , and c be the corresponding elements of $\pi_1(P, p)$. We assume that a , b , and c satisfy the relations $a, b, c \neq 1$ and $abc = 1$. Let $\langle \cdot, \cdot \rangle$ be the intersection form on $\pi_1(P, p)$. Then for $\hat{\sigma} := \hat{\sigma}_{\Gamma^*}$*

1. $\hat{\sigma}(ab) = \hat{\sigma}(a) + \hat{\sigma}(b)$ if the elements a and b can be represented by a pair of simple contours in P intersecting in exactly one point p with $\langle a, b \rangle \neq 0$,
2. $\hat{\sigma}(ab) = \hat{\sigma}(a) + \hat{\sigma}(b) + 1$ if the elements a and b can be represented by a pair of simple contours in P intersecting in exactly one point p with $\langle a, b \rangle = 0$ and placed in a neighbourhood of the point p as shown in Figure 3.
3. $\hat{\sigma}(ab) = \hat{\sigma}(a) + \hat{\sigma}(b) - 1$ if the elements a and b can be represented by a pair of simple contours in P intersecting in exactly one point p with $\langle a, b \rangle = 0$ and placed in a neighbourhood of the point p as shown in Figure 4.
4. for any standard basis

$$v = \{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\}$$

of $\pi_1(P, p)$ we have

$$\sum_{i=g+1}^n \hat{\sigma}(c_i) = (2 - 2g) - (n - g).$$

Proof. According to Theorem 3.3 either the set

$$V := \{\Phi^{-1}(a), \Phi^{-1}(b), \Phi^{-1}(c)\}$$

or the set

$$V^{-1} := \{\Phi^{-1}(a^{-1}), \Phi^{-1}(b^{-1}), \Phi^{-1}(c^{-1})\}$$

is sequential. This sequential set can be of type $(0, k, m)$ (with $k + m = 3$) or of type $(1, 1, 0)$. If V is a sequential set of type $(1, 1, 0)$, then according to Lemma 3.9 we obtain

$$\hat{\sigma}(ab) = \hat{\sigma}(a) + \hat{\sigma}(b).$$

If V is a sequential set of type $(0, k, m)$, then according to Lemma 3.8 we obtain

$$\hat{\sigma}(ab) = \hat{\sigma}(a) + \hat{\sigma}(b) + 1.$$

If V^{-1} is a sequential set of type $(0, k, m)$, then according to Lemma 3.8 we obtain

$$\hat{\sigma}(b^{-1}a^{-1}) = \hat{\sigma}(a^{-1}) + \hat{\sigma}(b^{-1}) + 1$$

and hence

$$\begin{aligned} -\hat{\sigma}(ab) &= \hat{\sigma}((ab)^{-1}) = \hat{\sigma}(b^{-1}a^{-1}) \\ &= \hat{\sigma}(a^{-1}) + \hat{\sigma}(b^{-1}) + 1 \\ &= -\hat{\sigma}(a) - \hat{\sigma}(b) + 1 \\ &= -(\hat{\sigma}(a) + \hat{\sigma}(b) - 1). \end{aligned}$$

To prove the fourth property of $\hat{\sigma}$ we consider the sequential set that corresponds to the standard basis v and apply Lemma 3.10. ■

We now formalize the properties of the function $\hat{\sigma}$ in the following definition:
Definition 4.2. We denote by $\pi_1^0(P, p)$ the set of all non-trivial elements of $\pi_1(P, p)$ that can be represented by simple contours. An m -Arf function is a function

$$\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}_m$$

satisfying the following conditions

1. $\sigma(bab^{-1}) = \sigma(a)$ for any elements $a, b \in \pi_1^0(P, p)$,
2. $\sigma(a^{-1}) = -\sigma(a)$ for any element $a \in \pi_1^0(P, p)$,
3. $\sigma(ab) = \sigma(a) + \sigma(b)$ for any elements a and b which can be represented by a pair of simple contours in P intersecting in exactly one point p with $\langle a, b \rangle \neq 0$,
4. $\sigma(ab) = \sigma(a) + \sigma(b) - 1$ for any elements $a, b \in \pi_1^0(P, p)$ such that the element ab is in $\pi_1^0(P, p)$ and the elements a and b can be represented by a pair of simple contours in P intersecting in exactly one point p with $\langle a, b \rangle = 0$ and placed in a neighbourhood of the point p as shown in Figure 4.

Remark. One can prove that in the case $m = 2$ there is a 1-1-correspondence between the 2-Arf functions in the sense of Definition 4.2 and Arf functions in the sense of [6], Chapter 1, Section 7. Namely, a function $\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}_2$ is a 2-Arf function if and only if $\omega = 1 - \sigma$ is an Arf function in the sense of [6].

The following property of m -Arf functions follows immediately from Properties 4 and 2 in Definition 4.2:

Proposition 4.2. *The equation $\sigma(ab) = \sigma(a) + \sigma(b) + 1$ is satisfied for any elements $a, b \in \pi_1^0(P, p)$ such that the element ab is in $\pi_1^0(P, p)$ and the elements a and b can be represented by a pair of simple contours in P intersecting in exactly one point p with $\langle a, b \rangle = 0$ and placed in a neighbourhood of the point p as shown in Figure 3.*

Proposition 4.3. *For any standard basis*

$$v = \{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\}$$

of $\pi_1(P, p)$ we have

$$\sum_{i=g+1}^n \sigma(c_i) = (2 - 2g) - (n - g).$$

Proof. We discuss the case $g = 0$ first, and then we reduce the general case to the case $g = 0$.

- Let $g = 0$. We prove that the statement is true for lifts of sequential sets of type $(0, l_h, l_p)$ by induction on $l_h + l_p$. In the case $l_h + l_p = 3$ Proposition 4.2 implies

$$\sigma(c_1 c_2) = \sigma(c_1) + \sigma(c_2) + 1,$$

while Property 2 implies

$$\sigma(c_1 c_2) = \sigma(c_3^{-1}) = -\sigma(c_3).$$

Combining these two equations we obtain

$$\sigma(c_1) + \sigma(c_2) + \sigma(c_3) = -1.$$

Assume that the statement is true for $l_h + l_p \leq n - 1$ and consider the case $l_h + l_p = n$. By our assumption

$$\sigma(c_1 \cdot c_2) + \sigma(c_3) + \dots + \sigma(c_n) = 2 - (n - 1) = (2 - n) + 1.$$

Moreover, by Proposition 4.2 we have

$$\sigma(c_1 c_2) = \sigma(c_1) + \sigma(c_2) + 1,$$

The last two equations imply that

$$\sum_{i=1}^n \sigma(c_i) = 2 - n.$$

- We now consider the general case. The set

$$(a_1, b_1 a_1^{-1} b_1^{-1}, \dots, a_g, b_g a_g^{-1} b_g^{-1}, c_{g+1}, \dots, c_n)$$

is a standard basis of a surface of type $(0, 2g + l_h, l_p)$, hence

$$\sum_{i=1}^g (\sigma(a_i) + \sigma(b_i a_i^{-1} b_i^{-1})) + \sum_{i=g+1}^n \sigma(c_i) = 2 - (n + g) = (2 - 2g) - (n - g).$$

From Properties 1 and 2 of m -Arf functions we obtain that

$$\sigma(b_i a_i^{-1} b_i^{-1}) = \sigma(a_i^{-1}) = -\sigma(a_i),$$

and hence

$$\sigma(a_i) + \sigma(b_i a_i^{-1} b_i^{-1}) = 0. \quad \blacksquare$$

Definition 4.3. Let $\hat{\sigma}_{\Gamma^*} : \pi_1(P, p) \rightarrow \mathbb{Z}_m$ be the function associated to a lift Γ^* as in definition 4.1, then the function $\sigma_{\Gamma^*} := \hat{\sigma}_{\Gamma^*}|_{\pi_1^0(P, p)}$ is an m -Arf function according to Lemma 4.1, 2.2, and 2.3. We call the function σ_{Γ^*} the m -Arf function associated to the lift Γ^* .

4.2. Higher Arf functions and Dehn twists.

We recall the definition of the Dehn twists ([2], [6] Chapter 1, Lemma 7.4).

Definition 4.4. Under Dehn twists we understand some transformations from a standard basis

$$v = \{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\}$$

of $\pi_1(P, p)$ to another standard basis

$$v' = \{a'_i, b'_i \ (i = 1, \dots, g), c'_i \ (i = g + 1, \dots, n)\}.$$

Any of these transformations induces a homotopy class of autohomeomorphisms of the surface P , which maps holes to holes and punctures to punctures. By Theorem of Dehn [2] the Dehn twists generate the whole group of such homotopy classes of autohomeomorphisms of P . There are Dehn twists of the following types:

1. $a'_1 = a_1 b_1.$
2. $a'_1 = (a_1 a_2) a_1 (a_1 a_2)^{-1},$
 $b'_1 = (a_1 a_2) a_1^{-1} b_1 a_2^{-1} (a_1 a_2)^{-1},$
 $a'_2 = a_1 a_2 a_1^{-1},$
 $b'_2 = b_2 a_2^{-1} a_1^{-1}.$
3. $a'_g = (b_g^{-1} c_1) b_g^{-1} (b_g^{-1} c_1)^{-1},$
 $b'_g = (b_g^{-1} c_1 b_g) c_1^{-1} b_g a_g b_g^{-1} (b_g^{-1} c_1 b_g)^{-1},$
 $c'_{g+1} = b_g^{-1} c_{g+1} b_g.$
4. $a'_k = a_{k+1},$
 $b'_k = b_{k+1},$
 $a'_{k+1} = (c_{k+1}^{-1} c_k) a_k (c_{k+1}^{-1} c_k)^{-1},$
 $b'_{k+1} = (c_{k+1}^{-1} c_k) b_k (c_{k+1}^{-1} c_k)^{-1}.$
5. $c'_k = c_{k+1},$
 $c'_{k+1} = c_{k+1}^{-1} c_k c_{k+1}.$

Here $c_i = [a_i, b_i]$ for $i = 1, \dots, g$, in 4 we consider $k \in \{1, \dots, g\}$, in 5 we consider $k \in \{g + 1, \dots, n\}$. If a'_i, b'_i resp. c'_i is not described explicitly, this means $a'_i = a_i, b'_i = b_i$ resp. $c'_i = c_i$.

Now we compute the values of σ on the standard basis v' from the values of σ on the standard basis v .

Lemma 4.4. *Let $\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}_m$ be an m -Arf function. Let D be a Dehn twist of the type described above. Suppose that D maps the standard basis*

$$v = \{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\}$$

into the standard basis

$$v' = D(v) = \{a'_i, b'_i \ (i = 1, \dots, g), c'_i \ (i = g + 1, \dots, n)\}.$$

Let

$$\{\alpha_i, \beta_i \ (i = 1, \dots, g), \gamma_i \ (i = g + 1, \dots, n)\}$$

resp.

$$\{\alpha'_i, \beta'_i \ (i = 1, \dots, g), \gamma'_i \ (i = g + 1, \dots, n)\}$$

be the values of σ on the elements of v resp. v' . Then for the Dehn twists of types 1–5 we obtain

1. $\alpha'_1 = \alpha_1 + \beta_1.$
2. $\beta'_1 = \beta_1 - \alpha_1 - \alpha_2 - 1,$
 $\beta'_2 = \beta_2 - \alpha_2 - \alpha_1 - 1.$
3. $\alpha'_g = -\beta_g,$
 $\beta'_g = \alpha_g - \gamma_{g+1} - 1.$
4. $\alpha'_k = \alpha_{k+1},$
 $\beta'_k = \beta_{k+1},$
 $\alpha'_{k+1} = \alpha_k,$
 $\beta'_{k+1} = \beta_k.$
5. $\gamma'_k = \gamma_{k+1},$
 $\gamma'_{k+1} = \gamma_k.$

Proof. We assume that the Dehn twist D belongs to one of the types described in the definition above. In the first case according to Property 3 of m -Arf functions we obtain

$$\sigma(a'_1) = \sigma(a_1 b_1) = \sigma(a_1) + \sigma(b_1).$$

In the second case according to Property 1 we obtain

$$\begin{aligned} \sigma(a'_1) &= \sigma((a_1 a_2) a_1 (a_1 a_2)^{-1}) = \sigma(a_1), \\ \sigma(b'_1) &= \sigma((a_1 a_2) a_1^{-1} b_1 a_2^{-1} (a_1 a_2)^{-1}) = \sigma(a_1^{-1} b_1 a_2^{-1}), \\ \sigma(a'_2) &= \sigma(a_1 a_2 a_1^{-1}) = \sigma(a_2), \\ \sigma(b'_2) &= \sigma(b_2 a_2^{-1} a_1^{-1}) \end{aligned}$$

According to Properties 3 and 2 we obtain

$$\begin{aligned} \sigma(a_1^{-1} b_1) &= \sigma(a_1^{-1}) + \sigma(b_1) = -\sigma(a_1) + \sigma(b_1), \\ \sigma(b_2 a_2^{-1}) &= \sigma(b_2) + \sigma(a_2^{-1}) = \sigma(b_2) - \sigma(a_2). \end{aligned}$$

Figure 5: Axes of $A_1^{-1}B_1$ and A_2^{-1}

Figure 6: Axes of C_1^{-1} and $B_g A_g B_g^{-1}$

In the following computations we illustrate the position of the contours on the surface with figures showing the position of the axes of the corresponding elements in Γ . Let

$$V = \{A_i, B_i \ (i = 1, \dots, g), C_i \ (i = g + 1, \dots, n)\}$$

be the sequential set corresponding to the standard basis v .

The mutual position of the axes of the elements $A_1^{-1}B_1$ and A_2^{-1} is as in Figure 5. According to Properties 4 and 2 we obtain

$$\begin{aligned} \sigma(b'_1) &= \sigma((a_1^{-1}b_1)a_2^{-1}) \\ &= \sigma(a_1^{-1}b_1) + \sigma(a_2^{-1}) - 1 \\ &= (\sigma(b_1) - \sigma(a_1)) - \sigma(a_2) - 1 \\ &= \sigma(b_1) - \sigma(a_1) - \sigma(a_2) - 1. \end{aligned}$$

Similarly

$$\sigma(b'_2) = \sigma(b_2) - \sigma(a_2) - \sigma(a_1) - 1.$$

In the third case we obtain according to Properties 2 and 1

$$\begin{aligned} \sigma(a'_g) &= \sigma((b_g^{-1}c_1)b_g^{-1}(b_g^{-1}c_1)^{-1}) = \sigma(b_g^{-1}) = -\sigma(b_g), \\ \sigma(b'_g) &= \sigma((b_g^{-1}c_1b_g)c_1^{-1}b_g a_g b_g^{-1}(b_g^{-1}c_1b_g)^{-1}) = \sigma(c_1^{-1}b_g a_g b_g^{-1}), \\ \sigma(c'_1) &= \sigma(b_g^{-1}c_1b_g) = \sigma(c_1). \end{aligned}$$

The mutual position of the axes of the elements C_1^{-1} and $B_g A_g B_g^{-1}$ is as in Figure 6. According to Properties 4 and 1 we obtain

$$\begin{aligned} \sigma(b'_g) &= \sigma(c_1^{-1} \cdot (b_g a_g b_g^{-1})) \\ &= \sigma(c_1^{-1}) + \sigma(b_g a_g b_g^{-1}) - 1 \\ &= \sigma(c_1^{-1}) + \sigma(a_g) - 1. \end{aligned}$$

In the fourth and fifth case computations are easy, we only use Property 1 of m -Arf functions. ■

4.3. Correspondence between higher Arf functions and higher spin structures.

Lemma 4.5. *The difference $\sigma_1 - \sigma_2 : \pi_1^0(P, p) \rightarrow \mathbb{Z}_m$ of two Arf functions σ_1 and σ_2 induces a linear function $\ell : H_1(P; \mathbb{Z}_m) \rightarrow \mathbb{Z}_m$.*

Proof. Let

$$\begin{aligned} v &= \{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\} \\ &= \{d_j \ (j = 1, \dots, n + g)\} \end{aligned}$$

be a standard basis of $\pi_1(P, p)$. For an element $a \in \pi_1(P, p)$ let us denote by $[a]$ the image of a in $H_1(P; \mathbb{Z}_m)$. Let

$$\begin{aligned} [v] &= \{[a_i], [b_i] \ (i = 1, \dots, g), [c_i] \ (i = g + 1, \dots, n)\} \\ &= \{[d_j] \ (j = 1, \dots, n + g)\} \end{aligned}$$

be the induced basis of $H_1(P; \mathbb{Z}_m)$.

Let us define $\delta : \pi_1^0(P, p) \rightarrow \mathbb{Z}_m$ by $\delta = \sigma_1 - \sigma_2$. Properties of the Arf functions σ_1 and σ_2 imply the following properties of the function δ :

1. $\delta(bab^{-1}) = \delta(a)$,
2. $\delta(a^{-1}) = -\delta(a)$,
3. $\delta(ab) = \delta(a) + \delta(b)$ if the elements a and b can be represented by a pair of simple contours in P intersecting in exactly one point p with $\langle a, b \rangle \neq 0$,
4. $\delta(ab) = \delta(a) + \delta(b)$ if the elements a and b can be represented by a pair of simple contours in P intersecting in exactly one point p with $\langle a, b \rangle = 0$ and placed in a neighbourhood of the point p as shown in Figure 4.

Let us define a function $\ell : H_1(P; \mathbb{Z}_m) \rightarrow \mathbb{Z}_m$ on $[v]$ by

$$\ell[d_j] = \delta(d_j)$$

for all $j = 1, \dots, n + g$ and then extend this function linearly on the whole $H_1(P; \mathbb{Z}_m)$. (Here we write $\ell[c]$ instead of $\ell([c])$ to simplify the notation.) The linearity of ℓ implies the following properties:

1. $\ell[bab^{-1}] = \ell([b] + [a] - [b]) = \ell[a]$,
2. $\ell[a^{-1}] = \ell(-[a]) = -\ell[a]$,
3. $\ell[ab] = \ell[a] + \ell[b]$ if the elements a and b can be represented by a pair of simple contours in P intersecting in exactly one point p with $\langle a, b \rangle \neq 0$,

4. $\ell[ab] = \ell[a] + \ell[b]$ if the elements a and b can be represented by a pair of simple contours in P intersecting in exactly one point p with $\langle a, b \rangle = 0$ and placed in a neighbourhood of the point p as shown in Figure 4.

Claim: We claim that $\ell[a] = \delta(a)$ for any element $a \in \pi_1^0(P, p)$.

Observation: We first observe that if a standard basis

$$\begin{aligned} v' &= \{a'_i, b'_i \ (i = 1, \dots, g), c'_i \ (i = g + 1, \dots, n)\} \\ &= \{d'_j \ (j = 1, \dots, n + g)\} \end{aligned}$$

is the image of the standard basis v under a Dehn twist, then

$$\ell[d'_j] = \delta(d'_j)$$

for all $j = 1, \dots, n + g$. Indeed, for the Dehn twists of type 1, 2, and 3 we obtain by Lemma 4.4 and by linearity of ℓ

1. $\delta(a'_1) = \delta(a_1) + \delta(b_1)$,
 $\ell[a'_1] = \ell[a_1 b_1] = \ell[a_1] + \ell[b_1]$,
2. $\delta(b'_1) = \delta(b_1) - \delta(a_1) - \delta(a_2)$,
 $\ell[b'_1] = \ell[(a_1 a_2) a_1^{-1} b_1 a_2^{-1} (a_1 a_2)^{-1}] = \ell[b_1] - \ell[a_1] - \ell[a_2]$,
 $\delta(b'_2) = \delta(b_2) - \delta(a_2) - \delta(a_1)$,
 $\ell[b'_2] = \ell[b_2 a_2^{-1} a_1^{-1}] = \ell[b_2] - \ell[a_1] - \ell[a_2]$,
3. $\delta(a'_g) = -\delta(b_g)$,
 $\ell[a'_g] = \ell[(b_g^{-1} c_1) b_g^{-1} (b_g^{-1} c_1)^{-1}] = -\ell[b_g]$,
 $\delta(b'_g) = \delta(a_g) - \delta(c_1)$,
 $\ell[b'_g] = \ell[(b_g^{-1} c_1 b_g) c_1^{-1} b_g a_g b_g^{-1} (b_g^{-1} c_1 b_g)^{-1}] = \ell[a_g] - \ell[c_1]$.

Here if $\delta(d'_j)$ and $\ell[d'_j]$ are not described explicitly, this means $\delta(d'_j) = \delta(d_j)$ and $\ell[d'_j] = \ell[d_j]$.

Let a be any contour not belonging to the kernel of the intersection form. Then a is an element a'_1 in some standard basis v' of $\pi_1(P, p)$. By Theorem of Dehn [2] the standard basis v' of $\pi_1(P, p)$ can be obtained from v as an image under a sequence of Dehn twists. Then the observation implies that $\delta(a) = \ell[a]$. Similarly any simple contour c homologous to a hole or a puncture is an element c'_{g+1} in some standard basis v' of $\pi_1(P, p)$, hence $\delta(c) = \ell[c]$. Let us now consider any simple contour c . We can express the element c as a product of elements of some standard basis

$$\begin{aligned} v' &= \{a'_i, b'_i \ (i = 1, \dots, g), c'_i \ (i = g + 1, \dots, n)\} \\ &= \{d'_j \ (j = 1, \dots, n + g)\} \end{aligned}$$

of $\pi_1(P, p)$. Using the properties of the functions δ and ℓ we compute $\delta(c)$ as a linear combination of $\delta(d'_j)$ and $\ell[c]$ as the linear combination of $\ell[d'_j]$ with the same coefficients. For example for the contour $c = c'_{g+1} c'_{g+2}$ we compute

$$\begin{aligned} \delta(c) &= \delta(c'_{g+1}) + \delta(c'_{g+2}), \\ \ell[c] &= \ell[c'_{g+1}] + \ell[c'_{g+2}]. \end{aligned}$$

On the other hand according to the observation $\delta(d'_j) = \ell[d'_j]$, hence $\delta(c) = \ell[c]$. So we have proved our claim. Hence the function $\delta = \sigma_1 - \sigma_2$ induces a linear function on $H_1(P; \mathbb{Z}_m)$.

On the contrary, if σ_0 is an m -Arf function on P and ℓ is a linear function on $H_1(P; \mathbb{Z}_m)$, then the function $\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}_m$ defined by

$$\sigma(a) = \sigma_0(a) + \ell[a]$$

is an m -Arf function on P . Using the properties of the m -Arf function σ_0 and linearity of the function ℓ we can prove that the function σ also has the properties of m -Arf functions. For example, we show Property 4: If $\langle c_1, c_2 \rangle = 0$ and the elements c_1 and c_2 can be represented by a pair of simple contours in P intersecting in exactly one point p and placed in a neighbourhood of the point p as is shown in Figure 4, then

$$\sigma(c_1 c_2) = \sigma(c_1) + \sigma(c_2) - 1.$$

Linearity of the function ℓ and Property 4 for σ_0 imply

$$\begin{aligned} \sigma(c_1 c_2) &= \sigma_0(c_1 c_2) + \ell[c_1 c_2] \\ &= (\sigma_0(c_1) + \sigma_0(c_2) - 1) + (\ell[c_1] + \ell[c_2]) \\ &= \sigma(c_1) + \sigma(c_2) - 1. \end{aligned}$$

The proofs of the other properties are similar. ■

Corollary 4.6. *The set $\text{Arf}^{P,m}$ of all m -Arf functions on $\pi_1^0(P, p)$ has a structure of an affine space, i.e. the set $\{\sigma - \sigma_0 \mid \sigma \in \text{Arf}^{P,m}\}$ is a free module over \mathbb{Z}_m for any $\sigma_0 \in \text{Arf}^{P,m}$.*

Corollary 4.7. *An m -Arf function is uniquely determined by its values on the elements of some standard basis of $\pi_1(P, p)$.*

Corollary 4.8. *Let P be a surface of type (g, l_h, l_p) . Then the number of different m -Arf functions on $\pi_1^0(P, p)$ is equal to*

- $m^{2g+l_h+l_p-1}$, if $l_h + l_p > 0$,
- $m^{2g+l_h+l_p}$, if $l_h + l_p = 0$ and $2g - 2 = 0 \pmod{m}$,
- 0 , otherwise.

Theorem 4.9. *There is a 1-1-correspondence between*

- 1) m -spin structures on $P = \mathbb{H}/\Gamma$.
- 2) lifts of Γ into G_m ,
- 3) m -Arf functions $\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}_m$.

Proof. According to Proposition 3.1 there is a 1-1-correspondence between m -spin structures on P and the lifts of Γ into G_m . In Definition 4.3 we attached to any lift Γ^* of Γ into G_m an m -Arf function σ_{Γ^*} . On the other hand we can attach to any m -Arf function σ a subset of G_m

$$\Gamma_\sigma^* := \{g \in G_m \mid \pi(g) \in \Gamma, s_m(g) = \sigma(\Phi(\pi(g)))\},$$

where $\pi : G_m \rightarrow G$ is the covering map. It remains to prove that this subset of G_m is actually a lift of Γ . Let

$$\begin{aligned} v &= \{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\} \\ &= \{d_j \ (j = 1, \dots, n + g)\} \end{aligned}$$

be a standard basis of $\pi_1(P, p)$ and let

$$\begin{aligned} \bar{V} &= \{\bar{A}_i, \bar{B}_i \ (i = 1, \dots, g), \bar{C}_i \ (i = g + 1, \dots, n)\} \\ &= \{\bar{D}_j \ (j = 1, \dots, n + g)\} \\ &= \{\Phi^{-1}(d_j) \ (j = 1, \dots, n + g)\} \end{aligned}$$

be the corresponding sequential set. Let

$$\begin{aligned} V &= \{A_i, B_i \ (i = 1, \dots, g), C_i \ (i = g + 1, \dots, n)\} \\ &= \{D_j \ (j = 1, \dots, n + g)\} \end{aligned}$$

be a lift of the sequential set \bar{V} , i.e. $\pi(D_j) = \bar{D}_j$, such that $s_m(D_j) = \sigma(d_j)$. Then we obtain

$$\sum_{i=g+1}^n s_m(C_i) = \sum_{i=g+1}^n \sigma(c_i) = (2 - 2g) - (n - g),$$

hence by Lemma 3.10 we obtain

$$\prod_{i=1}^g [A_i, B_i] \cdot \prod_{i=g+1}^n C_i = e.$$

This implies according to Lemma 3.7 that the subgroup Γ^* of G_m generated by V is a lift of Γ into G_m . Let us compare the corresponding Arf function σ_{Γ^*} with the Arf function σ . We have

$$\sigma_{\Gamma^*}(d_j) = s_m(D_j) = \sigma(d_j)$$

for all j i.e. the Arf functions σ_{Γ^*} and σ coincide on the standard basis v . Thus by Corollary 4.7 the Arf functions σ_{Γ^*} and σ coincide on the whole $\pi_1^0(P, p)$. From the definition of σ_{Γ^*} and Γ^* we see that this implies that $\Gamma^* = \Gamma_\sigma^*$, hence Γ_σ^* is indeed a lift of Γ into G_m . It is clear from the definitions that the mappings $\Gamma^* \mapsto \sigma_{\Gamma^*}$ and $\sigma \mapsto \Gamma_\sigma^*$ are inverse to each other. ■

Remark. Let us define an ∞ -Arf function as a function $\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}$ satisfying the four properties in Definition of m -Arf functions (Definition 4.2). Then slightly modifying the previous discussion of m -Arf functions we obtain similar results for ∞ -Arf functions:

- 1) The set $\text{Arf}^{P, \infty}$ of all ∞ -Arf functions on $\pi_1^0(P, p)$ has a structure of an affine space associated to $H^1(P; \mathbb{Z})$.

- 2) For a surface $P = \mathbb{H}/\Gamma$ there is a 1-1-correspondence between ∞ -Arf functions $\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}$ and lifts of the group Γ into the universal cover \tilde{G} of $\mathrm{PSL}(2, \mathbb{R})$.

Corollary 4.10. *The set of all m -spin structures on P has a structure of an affine space.*

Corollary 4.11. *Let P be a surface of type (g, l_h, l_p) . Then the number of different m -spin structures on P is equal to*

- $m^{2g+l_h+l_p-1}$, if $l_h + l_p > 0$,
- $m^{2g+l_h+l_p}$, if $l_h + l_p = 0$ and $2g - 2 = 0 \pmod{m}$,
- 0 , otherwise.

5. Moduli spaces of higher spin structures

We study the moduli space of m -spin hyperbolic Riemann surfaces, i.e. hyperbolic Riemann surfaces with an m -spin structure. Using Proposition 3.1, we define the moduli space of m -spin structures as the space of conjugacy classes of subgroups Γ^* in G_m such that the restriction of the covering map $G_m \rightarrow G = \mathrm{PSL}(2, \mathbb{R})$ to Γ^* is an isomorphism between Γ^* and a Fuchsian group Γ .

The projection $\Gamma^* \mapsto \Gamma$ from the moduli space of Riemann surfaces with an m -spin structure to the moduli space of Riemann surfaces is a finite ramified covering.

5.1. Topological classification of higher Arf functions.

There is a 1-1-correspondence (see Theorem 4.9) between m -spin structures on a surface P and m -Arf functions on $\pi_1^0(P, p)$. This correspondence allows us to reduce the problem of finding the number of connected components of the moduli space of higher spin Riemann surfaces to the problem of finding the number of orbits of the action of the group of autohomeomorphisms on the set of m -Arf functions. We describe the orbit of an m -Arf function under the action of the group of homotopy classes of surface autohomeomorphisms.

Let P be a Riemann surface of type (g, l_h, l_p) with $l_h + l_p = n - g$. Let $p \in P$.

Definition 5.1. Let $\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}_m$ be an m -Arf function. For $g = 1$ we define the *Arf invariant* $\delta = \delta(P, \sigma)$ as

$$\delta = \mathrm{gcd}(m, \sigma(a_1), \sigma(b_1), \sigma(c_2) + 1, \dots, \sigma(c_n) + 1),$$

where

$$\{a_1, b_1, c_i \ (i = 2, \dots, n)\}$$

is a standard basis of the fundamental group $\pi_1(P, p)$. (The Arf invariant δ is well defined as it is invariant under the transformations described in Lemma 4.4.) For $g > 1$ and even m we define the *Arf invariant* $\delta = \delta(P, \sigma)$ as $\delta = 0$ if there is a standard basis

$$\{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\}$$

of the fundamental group $\pi_1(P, p)$ such that

$$\sum_{i=1}^g (1 - \sigma(a_i))(1 - \sigma(b_i)) = 0 \pmod{2}$$

and as $\delta = 1$ otherwise. For $g > 1$ and odd m we set $\delta = 0$.

Definition 5.2. Let $\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}_m$ be an m -Arf function and

$$v = \{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\}$$

a standard basis of the fundamental group $\pi_1(P, p)$. In the standard basis v the elements $c_{g+1}, \dots, c_{g+l_h}$ correspond to the holes and the elements c_{g+l_h+1}, \dots, c_n correspond to the punctures. The set of holes

$$c_{g+1}, \dots, c_{g+l_h}$$

is divided into m sets

$$D_j = \{c_i \mid \sigma(c_i) = j, \ g < i \leq g + l_h\}.$$

We denote by $n_j^h = n_j^h(P, \sigma)$, $j \in \mathbb{Z}_m$, the cardinality of the set D_j . Similarly, the punctures

$$c_{g+l_h+1}, \dots, c_n$$

are divided into m sets of the form

$$E_j = \{c_i \mid \sigma(c_i) = j, \ g + l_h < i \leq n\}.$$

Let $n_j^p = n_j^p(P, \sigma)$, $j \in \mathbb{Z}_m$, be the cardinality of the set E_j . We have

$$\sum_{j \in \mathbb{Z}_m} n_j^h = l_h \quad \text{and} \quad \sum_{j \in \mathbb{Z}_m} n_j^p = l_p.$$

By the *type of the m -Arf function* (P, σ) we mean the tuple

$$(g, \delta, n_0^h, \dots, n_{m-1}^h, n_0^p, \dots, n_{m-1}^p),$$

where δ is the Arf invariant of σ defined above.

Lemma 5.1. *Assume that $g > 1$. Let $\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}_m$ be an m -Arf function, then there is a standard basis*

$$v = \{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\}$$

of $\pi_1(P, p)$ such that

$$(\sigma(a_1), \sigma(b_1), \dots, \sigma(a_g), \sigma(b_g)) = (0, \xi, 1, \dots, 1)$$

with $\xi \in \{0, 1\}$ and

$$\sigma(c_{g+1}) \leq \dots \leq \sigma(c_{g+l_h}), \quad \sigma(c_{g+l_h+1}) \leq \dots \leq \sigma(c_n).$$

If m is odd or there is a contour around a hole or a puncture such that the value of σ on this contour is even, then the basis can be chosen in such a way that $\xi = 1$.

Proof.

a) Let us fix some standard basis

$$v_0 = \{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\}$$

and consider the sequence of values of the Arf function σ on this basis v_0

$$\begin{aligned} & (\alpha_1, \beta_1, \dots, \alpha_g, \beta_g, \gamma_{g+1}, \dots, \gamma_n) \\ & = (\sigma(a_1), \sigma(b_1), \dots, \sigma(a_g), \sigma(b_g), \sigma(c_{g+1}), \dots, \sigma(c_n)). \end{aligned}$$

If m is even and there is a hole or a puncture, such that for the corresponding contour c the value $\sigma(c)$ is even, then we can choose the standard basis v_0 in such a way, that the value $\sigma(c_{g+1})$ is even. Any other standard basis v is an image of the basis v_0 under an autohomeomorphisms of the surface, i.e. under a sequence of Dehn twist. Hence according to Lemma 4.4 the sequence of values of σ on the basis v is the image of the corresponding sequence with respect to the basis v_0 under the group generated by the transformations that change the first $2g$ components $(\alpha_1, \beta_1, \dots, \alpha_g, \beta_g)$ as follows

- 1a. $(\alpha_1, \beta_1, \dots, \alpha_i, \beta_i, \dots, \alpha_g, \beta_g)$
 $\mapsto (\alpha_1, \beta_1, \dots, \alpha_i \pm \beta_i, \beta_i, \dots, \alpha_g, \beta_g),$
- 1b. $(\alpha_1, \beta_1, \dots, \alpha_i, \beta_i, \dots, \alpha_g, \beta_g)$
 $\mapsto (\alpha_1, \beta_1, \dots, \alpha_i, \beta_i \pm \alpha_i, \dots, \alpha_g, \beta_g),$
2. $(\alpha_1, \beta_1, \dots, \alpha_i, \beta_i, \dots, \alpha_j, \beta_j, \dots, \alpha_g, \beta_g)$
 $\mapsto (\alpha_1, \beta_1, \dots, \alpha_i, \beta_i - \alpha_j - 1, \dots, \alpha_j, \beta_j - \alpha_i - 1, \dots, \alpha_g, \beta_g),$
3. $(\alpha_1, \beta_1, \dots, \alpha_{g-1}, \beta_{g-1}, \alpha_g, \beta_g)$
 $\mapsto (\alpha_1, \beta_1, \dots, \alpha_{g-1}, \beta_{g-1}, -\beta_g, \alpha_g - \gamma_{g+1} - 1),$
4. $(\alpha_1, \beta_1, \dots, \alpha_i, \beta_i, \dots, \alpha_j, \beta_j, \dots, \alpha_g, \beta_g)$
 $\mapsto (\alpha_1, \beta_1, \dots, \alpha_j, \beta_j, \dots, \alpha_i, \beta_i, \dots, \alpha_g, \beta_g),$
- 5a. $(\alpha_1, \beta_1, \dots, \alpha_i, \beta_i, \dots, \alpha_g, \beta_g)$
 $\mapsto (\alpha_1, \beta_1, \dots, -\alpha_i, -\beta_i, \dots, \alpha_g, \beta_g),$
- 5b. $(\alpha_1, \beta_1, \dots, \alpha_i, \beta_i, \dots, \alpha_g, \beta_g)$
 $\mapsto (\alpha_1, \beta_1, \dots, -\beta_i, \alpha_i, \dots, \alpha_g, \beta_g)$

and change $(\gamma_{g+1}, \dots, \gamma_n)$ by all possible permutations of $(\gamma_{g+1}, \dots, \gamma_{g+l_h})$ and $(\gamma_{g+l_h+1}, \dots, \gamma_n)$. The inequalities between the values of σ on the elements c_i are easy to satisfy, because the transformation group contains all possible permutations of $(\gamma_{g+1}, \dots, \gamma_{g+l_h})$ and $(\gamma_{g+l_h+1}, \dots, \gamma_n)$. Our aim is to show that, if m is odd or one of the numbers $\gamma_{g+1}, \dots, \gamma_n$ is even, any tuple $(\alpha_1, \beta_1, \dots, \alpha_g, \beta_g)$ can be transformed into the $2g$ -tuple

$$(0, 1, 1, \dots, 1),$$

while otherwise any such tuple can be transformed into one of the tuples

$$(0, 0, 1, \dots, 1) \quad \text{or} \quad (0, 1, 1, \dots, 1).$$

- b) We claim that the group of transformations described in (a) contains the transformation of the form

$$(\dots, \alpha_i, \beta_i, \dots, \alpha_j, \beta_j, \dots) \mapsto (\dots, \alpha_i, \beta_i - 2, \dots, \alpha_j, \beta_j, \dots) :$$

Let us assume $(i, j) = (1, 2)$ in order to simplify the notation. We apply transformations 2, 5a, again 2 and again 5a and obtain

$$\begin{aligned} & (\alpha_1, \beta_1, \alpha_2, \beta_2, \dots) \\ & \mapsto (\alpha_1, \beta_1 - \alpha_2 - 1, \alpha_2, \beta_2 - \alpha_1 - 1, \dots) \\ & \mapsto (\alpha_1, \beta_1 - \alpha_2 - 1, \alpha_2, \beta_2 - \alpha_1 - 1, \dots) \\ & \mapsto (\alpha_1, \beta_1 - \alpha_2 - 1, -\alpha_2, -(\beta_2 - \alpha_1 - 1), \dots) \\ & \mapsto (\alpha_1, \beta_1 - \alpha_2 - 1 - (-\alpha_2) - 1, -\alpha_2, -\beta_2 + \alpha_1 + 1 - \alpha_1 - 1, \dots) \\ & = (\alpha_1, \beta_1 - 2, -\alpha_2, -\beta_2, \dots) \\ & \mapsto (\alpha_1, \beta_1 - 2, \alpha_2, \beta_2, \dots). \end{aligned}$$

- c) Furthermore, we claim that the group of transformations contains a transformation of the form

$$(\alpha_1, \beta_1, \alpha_2, \beta_2, \dots) \mapsto (0, \xi, 1, 1, \dots), \quad \text{where } \xi \in \{0, 1\} :$$

With the help of the transformation described in (b) we can transform

$$(\alpha_1, \beta_1, \alpha_2, \beta_2, \dots) \mapsto (\alpha'_1, \beta'_1, \alpha'_2, \beta'_2, \dots), \quad \text{where } \alpha'_1, \beta'_1, \alpha'_2, \beta'_2 \in \{0, 1\}.$$

Applying the inverse of transformation 2 we obtain

$$(0, 0, 0, 0, \dots) \mapsto (0, 1, 0, 1, \dots).$$

Applying transformation 1a resp. 1b we obtain

$$(0, 1, \dots) \mapsto (1, 1, \dots) \quad \text{and} \quad (1, 0, \dots) \mapsto (1, 1, \dots)$$

- d) By successive application of the transformation described in (c) we obtain that any $2g$ -tuple can be transformed to a tuple of the form $(0, \xi, 1, \dots, 1)$.
- e) If $m = 2r + 1$ is odd, then we use the transformation described in (b) to map

$$\begin{aligned} (0, 1, 1, \dots, 1) & \mapsto (0, 1 - 2 \cdot (r + 1), 1, \dots, 1) \\ & = (0, -m, 1, \dots, 1) = (0, 0, 1, \dots, 1), \end{aligned}$$

hence the $2g$ -tuple $(0, 0, 1, \dots, 1)$ can be transformed into $(0, 1, 1, \dots, 1)$.

- f) If m and $\gamma_{g+1} = 2r$ are even, then we use the transformation 4, the transformation 3, successive application of the transformation described in (b), and the transformation 4 again to map

$$\begin{aligned} (0, 0, 1, \dots, 1) & \mapsto (1, \dots, 1, 0, 0) \\ & \mapsto (1, \dots, 1, 0, 0 - 2r - 1) \\ & \mapsto (1, \dots, 1, 0, 1), \\ & \mapsto (0, 1, 1, \dots, 1), \end{aligned}$$

hence also in this case the $2g$ -tuple $(0, 0, 1, \dots, 1)$ can be transformed into the tuple $(0, 1, 1, \dots, 1)$. ■

Lemma 5.2. *Assume that $g = 1$. Let $\sigma : \pi_1^0(P, p) \rightarrow \mathbb{Z}_m$ be an m -Arf function, then there is a standard basis*

$$v = \{a_1, b_1, c_i \ (i = 2, \dots, n)\}$$

of $\pi_1(P, p)$ such that

$$(\sigma(a_1), \sigma(b_1)) = (\delta, 0),$$

where $\delta = \gcd(m, \alpha_1, \beta_1, \gamma_2 + 1, \dots, \gamma_n + 1)$, and

$$\sigma(c_2) \leq \dots \leq \sigma(c_{l_h+1}), \quad \sigma(c_{l_h+2}) \leq \dots \leq \sigma(c_n).$$

Proof. Let us fix some standard basis

$$v_0 = \{a_1, b_1, c_i \ (i = 2, \dots, n)\}$$

and consider the sequence of values of the Arf function σ on this basis v_0

$$(\alpha_1, \beta_1, \gamma_2, \dots, \gamma_n) = (\sigma(a_1), \sigma(b_1), \sigma(c_2), \dots, \sigma(c_n)).$$

Any other standard basis v is an image of the basis v_0 under an autohomeomorphism of the surface, i.e. under a sequence of Dehn twist. Hence according to Lemma 4.4 the sequence of values of σ on the basis v is the image of the corresponding sequence with respect to the basis v_0 under the group generated by the transformations that change the first two components (α_1, β_1) as follows

- 1a. $(\alpha_1, \beta_1) \mapsto (\alpha_1 \pm \beta_1, \beta_1)$,
- 1b. $(\alpha_1, \beta_1) \mapsto (\alpha_1, \beta_1 \pm \alpha_1)$,
- 3. $(\alpha_1, \beta_1) \mapsto (-\beta_1, \alpha_1 - \gamma_2 - 1)$,
- 5a. $(\alpha_1, \beta_1) \mapsto (-\alpha_1, -\beta_1)$,
- 5b. $(\alpha_1, \beta_1) \mapsto (-\beta_1, \alpha_1)$.

and change $(\gamma_2, \dots, \gamma_n)$ by all possible permutations of

$$(\gamma_2, \dots, \gamma_{1+l_h}) \quad \text{and} \quad (\gamma_{1+l_h+1}, \dots, \gamma_n).$$

The inequalities between the values of σ on the elements c_i are easy to satisfy, because the transformation group contains all possible permutations of $(\gamma_2, \dots, \gamma_{1+l_h})$ and $(\gamma_{1+l_h+1}, \dots, \gamma_n)$. Using transformations 1a, 1b, 5a, 5b any tuple (α_1, β_1) can be transformed into the tuple $(\gcd(m, \alpha_1, \beta_1), 0)$. Using the transformation 3 any tuple (α_1, β_1) can be transformed into the tuple $(\gcd(m, \alpha_1, \beta_1, \gamma_2 + 1, \dots, \gamma_n + 1), 0)$. ■

Remark. An autohomeomorphism of a surface P induces an automorphism of m -spin structures on P . Let \mathcal{A} be the corresponding group of such automorphisms of m -spin structures on P . On the other hand, any autohomeomorphism generates an element of $\text{Sp}(2g, \mathbb{Z})$, where g is the genus of P . Lemmas 5, 5.2 imply that for two autohomeomorphisms the corresponding elements in \mathcal{A} differ if the corresponding elements in $\text{Sp}(2g, \mathbb{Z}_m)$ differ. Thus we obtain a homomorphism $f : \mathcal{A} \rightarrow \text{Sp}(2g, \mathbb{Z}_m)$. Using Dehn twists of types 1,2 and 4 we can show that f is an

epimorphism. Lemmas 5, 5.2 imply that $\ker(f) = d \cdot T$, where T is the group of all parallel translations on the affine space of all m -spin structures. Using Dehn twists of types 1–5 and Lemmas 5, 5.2 we are able to determine the number d . If $g > 1$ then $d = 2$ if m is even and all n are odd, and $d = 1$ otherwise. If $g = 1$ then $d = \gcd(m, \alpha_1, \beta_1, \gamma_2 + 1, \dots, \gamma_n + 1)$. An algebraic-geometric proof of this affirmation is contained in [14] (Lemma 3.3.6).

Theorem 5.3. *A tuple $t = (g, \delta, n_0^h, \dots, n_{m-1}^h, n_0^p, \dots, n_{m-1}^p)$, where*

$$\sum_{j \in \mathbb{Z}_m} n_j^h = l_h \quad \text{and} \quad \sum_{j \in \mathbb{Z}_m} n_j^p = l_p,$$

is the type of a hyperbolic m -Arf function on a Riemann surface of type (g, l_h, l_p) if and only if it has the following properties:

- (a) *If $g > 1$ and m is odd, then $\delta = 0$.*
- (b) *If $g > 1$ and m is even and $n_j^h + n_j^p \neq 0$ for some even $j \in \mathbb{Z}_m$, then $\delta = 0$.*
- (c) *If $g = 1$ then δ is a divisor of m and $\gcd(\{j + 1 \mid n_j^h + n_j^p \neq 0\})$.*
- (d) *The following degree condition is satisfied*

$$\sum_{j \in \mathbb{Z}_m} j \cdot (n_j^h + n_j^p) = (2 - 2g) - (l_h + l_p).$$

Proof. Let us first assume that the tuple t is the type of a hyperbolic m -Arf function on a Riemann surface of type (g, l_h, l_p) and that σ is such a function. Then Proposition 4.3 implies that

$$(2 - 2g) - (n - g) = \sum_{i=g+1}^n \sigma(c_i) = \sum_{j \in \mathbb{Z}_m} j \cdot (n_j^h + n_j^p).$$

Let us assume that $g > 1$. If m is odd or (m is even and $n_j^h + n_j^p \neq 0$ for some even $j \in \mathbb{Z}_m$), then according to Lemma 5.1 there is a standard basis

$$v = \{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\}$$

of $\pi_1(P, p)$ such that

$$(\sigma(a_1), \sigma(b_1), \dots, \sigma(a_g), \sigma(b_g)) = (0, 1, 1, \dots, 1),$$

hence $\delta(P, \sigma) = 0$ by definition. Now let us assume that $t = (g, \delta, n_j^h, n_j^p)$ is a tuple satisfying the conditions (1) and (2). Let us fix some standard basis

$$v_0 = \{a_i, b_i \ (i = 1, \dots, g), c_i \ (i = g + 1, \dots, n)\}$$

The condition (1) together with Proposition 4.3 and Corollary 4.7 imply that there exist Arf functions σ^0 and σ^1 such that $n_j^h(\sigma^\delta) = n_j^h$, $n_j^p(\sigma^\delta) = n_j^p$ for $j \in \mathbb{Z}_m$ and

$$(\sigma^\delta(a_1), \sigma^\delta(b_1), \dots, \sigma^\delta(a_g), \sigma^\delta(b_g)) = (0, 1 - \delta, 1, \dots, 1).$$

The equation $\delta(\sigma^0) = 0$ is satisfied by definition. It remains to prove, in the case that m is even and all γ_i are odd, that $\delta(\sigma^1) = 1$. To this end we observe, using the explicit description of the action of Dehn twists on m -Arf functions in Lemma 4.4, that the parity of the sum

$$\sum_{i=1}^g (1 - \sigma(a_i))(1 - \sigma(b_i))$$

is preserved under the Dehn twists and hence is equal to 1 modulo 2 for any standard basis.

In the case $g = 1$ the proof is similar. In this case we observe that

$$\gcd(m, \sigma(a_1), \sigma(b_1), \sigma(c_2) + 1, \dots, \sigma(c_n) + 1)$$

is preserved under the Dehn twists. ■

5.2. Connected components of the moduli space.

We recall the results on the moduli space of Riemann surfaces from [6]. Let $\Gamma_{g,n}$ be the group generated by the elements

$$v = \{a_1, b_1, \dots, a_g, b_g, c_{g+1}, \dots, c_n\}$$

with a single defining relation

$$\prod_{i=1}^g [a_i, b_i] \prod_{i=g+1}^n c_i = 1.$$

We denote by \tilde{T}_{g,l_h,l_p} the set of monomorphisms $\psi : \Gamma_{g,n} \rightarrow \text{Aut}(\mathbb{H})$ such that

$$\psi(v) = \{a_i^\psi, b_i^\psi \ (i = 1, \dots, g), c_i^\psi \ (i = g + 1, \dots, n)\}$$

is a sequential set of type (g, l_h, l_p) . Here $l_h + l_p = n - g$ and we assume that $6g + 3l_h + 2l_p > 6$.

The group $\text{Aut}(\mathbb{H})$ acts on \tilde{T}_{g,l_h,l_p} by conjugation. We set

$$T_{g,l_h,l_p} = \tilde{T}_{g,l_h,l_p} / \text{Aut}(\mathbb{H}).$$

We parametrise the space \tilde{T}_{g,l_h,l_p} by the fixed points and shift parameters of the elements of the sequential sets $\psi(v)$. We use here the following result similar to Theorem of Fricke and Klein [1].

Theorem 5.4. ([6] (Chapter 1, Theorem 4.1))

The space T_{g,l_h,l_p} is diffeomorphic to an open domain in $\mathbb{R}^{6g+3l_h+2l_p-6}$, which is homeomorphic to $\mathbb{R}^{6g+3l_h+2l_p-6}$.

For an element $\psi : \Gamma_{g,n} \rightarrow \text{Aut}(\mathbb{H})$ of $\widetilde{T}_{g,l_h,l_p}$ we write

$$\widetilde{\text{Mod}}^\psi = \widetilde{\text{Mod}}_{g,l_h,l_p}^\psi = \{\alpha \in \text{Aut}(\Gamma_{g,n}) \mid \psi \circ \alpha \in \widetilde{T}_{g,l_h,l_p}\}.$$

One can show that $\widetilde{\text{Mod}}^\psi$ does not depend on ψ , hence we write $\widetilde{\text{Mod}}$ instead of $\widetilde{\text{Mod}}^\psi$. Let $I\widetilde{\text{Mod}}$ be the subgroup of all inner automorphisms of $\Gamma_{g,n}$ and let

$$\text{Mod}_{g,l_h,l_p} = \text{Mod} = \widetilde{\text{Mod}}/I\widetilde{\text{Mod}}.$$

We now recall the description of the moduli space of Riemann surfaces

Theorem 5.5. ([6], Chapter 1, Section 5)

The group $\text{Mod} = \text{Mod}_{g,l_h,l_p}$ and the group of homotopy classes of orientation preserving autohomeomorphisms of the surface of type (g, l_h, l_p) are naturally isomorphic. The group Mod_{g,l_h,l_p} acts naturally on T_{g,l_h,l_p} by diffeomorphisms. This action is discrete. The quotient set $T_{g,l_h,l_p}/\text{Mod}_{g,l_h,l_p}$ can be identified naturally with the moduli space M_{g,l_h,l_p} of Riemann surfaces of type (g, l_h, l_p) .

Definition 5.3. We denote by

$$S_{g,l_h,l_p}^m(t) = S_{g,l_h,l_p}^m(g, \delta, n_0^h, \dots, n_{m-1}^h, n_0^p, \dots, n_{m-1}^p)$$

the set of all m -spin structures on all Riemann surfaces of type (g, l_h, l_p) such that the associated m -Arf function is of type

$$t = (g, \delta, n_0^h, \dots, n_{m-1}^h, n_0^p, \dots, n_{m-1}^p).$$

Theorem 5.6. *Let $t = (g, \delta, n_0^h, \dots, n_{m-1}^h, n_0^p, \dots, n_{m-1}^p)$ be a tuple that satisfies the conditions of Theorem 5.3, i.e. the space $S_{g,l_h,l_p}^m(t)$ is not empty. Then the space $S_{g,l_h,l_p}^m(t)$ is homeomorphic to $T_{g,l_h,l_p}/\text{Mod}_{g,l_h,l_p}^m(t)$, where T_{g,l_h,l_p} is homeomorphic to $\mathbb{R}^{6g+3l_h+2l_p-6}$ and $\text{Mod}_{g,l_h,l_p}^m(t)$ acts on T_{g,l_h,l_p} as a subgroup of finite index in the group Mod_{g,l_h,l_p} .*

Proof. Let us consider an element ψ of the space T_{g,l_h,l_p} . By definition ψ is an homomorphism $\psi : \Gamma_{g,n} \rightarrow \text{Aut}(\mathbb{H})$. To the homomorphism ψ we attach a Riemann surface $P_\psi = \mathbb{H}/\psi(\Gamma_{g,n})$, a standard basis

$$v_\psi = \{a_i^\psi, b_i^\psi \ (i = 1, \dots, g), c_i^\psi \ (i = g + 1, \dots, n)\}$$

of $\pi_1(P_\psi, p)$, and an m -Arf function σ_ψ on this surface given by

$$\begin{aligned} (\sigma_\psi(a_1^\psi), \sigma_\psi(b_1^\psi)) &= (\delta, 0) \quad \text{if } g = 1, \\ (\sigma_\psi(a_1^\psi), \sigma_\psi(b_1^\psi), \sigma_\psi(a_2^\psi), \sigma_\psi(b_2^\psi), \dots, \sigma_\psi(a_g^\psi), \sigma_\psi(b_g^\psi)) &= (0, 1 - \delta, 1, \dots, 1) \quad \text{if } g > 1, \\ (\sigma_\psi(c_{g+1}^\psi), \dots, \sigma_\psi(c_{g+l_h}^\psi)) &= (\underbrace{0, \dots, 0}_{n_0^h}, \underbrace{1, \dots, 1}_{n_1^h}, \dots, \underbrace{m-1, \dots, m-1}_{n_{m-1}^h}), \\ (\sigma_\psi(c_{g+l_h}^\psi), \dots, \sigma_\psi(c_n^\psi)) &= (\underbrace{0, \dots, 0}_{n_0^p}, \underbrace{1, \dots, 1}_{n_1^p}, \dots, \underbrace{m-1, \dots, m-1}_{n_{m-1}^p}). \end{aligned}$$

By Theorem 4.9, the m -Arf function σ_ψ on the surface P_ψ corresponds to an m -spin structure δ_ψ on P_ψ . The correspondence $\psi \mapsto \delta_\psi$ defines a map

$$T_{g,l_h,l_p} \rightarrow S_{g,l_h,l_p}^m(t).$$

According to Theorem 5.3 this map is surjective. Let $\text{Mod}_{g,l_h,l_p}^m(t)$ be the subgroup of $\text{Aut}(P_\psi) = \text{Mod}_{g,l_h,l_p}$ that preserves the m -Arf function σ_ψ . For any point in $S_{g,l_h,l_p}^m(t)$ its preimage in T_{g,l_h,l_p} consists of an orbit of the subgroup $\text{Mod}_{g,l_h,l_p}^m(t)$. Thus

$$S_{g,l_h,l_p}^m(t) = T_{g,l_h,l_p} / \text{Mod}_{g,l_h,l_p}^m(t). \quad \blacksquare$$

Summarizing the results of Theorems 5.3 and 5.6 we obtain the following

Theorem.

- 1) *Two m -spin structures are in the same connected component of the space of all m -spin structures on hyperbolic Riemann surfaces iff they are of the same type. In other words, the connected components of the space of all m -spin structures are those sets $S_{g,l_h,l_p}^m(t)$ that are not empty.*
- 2) *The set $S_{g,l_h,l_p}^m(t)$ is not empty iff $t = (g, \delta, n_0^h, \dots, n_{m-1}^h, n_0^p, \dots, n_{m-1}^p)$ has the following properties:*
 - (a) *If $g > 1$ and m is odd, then $\delta = 0$.*
 - (b) *If $g > 1$ and m is even and $n_j^h + n_j^p \neq 0$ for some even $j \in \mathbb{Z}_m$, then $\delta = 0$.*
 - (c) *If $g = 1$ then δ is a divisor of m and $\gcd(\{j + 1 \mid n_j^h + n_j^p \neq 0\})$.*
 - (d) *The following degree condition is satisfied*

$$\sum_{j \in \mathbb{Z}_m} j \cdot (n_j^h + n_j^p) = (2 - 2g) - (l_h + l_p).$$

- 3) *Any connected component $S_{g,l_h,l_p}^m(t)$ of the space of all m -spin structures on hyperbolic Riemann surfaces of type (g, l_h, l_p) is homeomorphic to*

$$\mathbb{R}^{6g+3l_h+2l_p-6} / \text{Mod}_{g,l_h,l_p}^m(t),$$

where $\text{Mod}_{g,l_h,l_p}^m(t)$ is a subgroup of finite index in the group Mod_{g,l_h,l_p} and acts discrete on $\mathbb{R}^{6g+3l_h+2l_p-6}$.
