Double Flag Varieties for a Symmetric Pair
and Finiteness of Orbits

Kyo Nishiyama∗ and Hiroyuki Ochiai†

Communicated by E. B. Vinberg

Abstract. Let $G$ be a reductive algebraic group over the complex number field, and $K = G^\theta$ be the fixed points of an involutive automorphism $\theta$ of $G$ so that $(G, K)$ is a symmetric pair.

We take parabolic subgroups $P$ and $Q$ of $G$ and $K$ respectively and consider a product of partial flag varieties $G/P$ and $K/Q$ with diagonal $K$-action. The double flag variety $G/P \times K/Q$ thus obtained is said to be of finite type if there are finitely many $K$-orbits on it. A triple flag variety $G/P_1 \times G/P_2 \times G/P_3$ is a special case of our double flag varieties, and there are many interesting works on the triple flag varieties.

In this paper, we study double flag varieties $G/P \times K/Q$ of finite type. We give efficient criterion under which the double flag variety is of finite type. The finiteness of orbits is strongly related to spherical actions of $G$ or $K$. For example, we show a partial flag variety $G/P$ is $K$-spherical if a product of partial flag varieties $G/P \times G/\theta(P)$ is $G$-spherical. We also give many examples of the double flag varieties of finite type, and for type $A_{III}$, we give a classification when $P = B$ is a Borel subgroup of $G$.

Mathematics Subject Classification 2000: Primary 14M15; secondary 53C35, 14M17.

Key Words and Phrases: Symmetric pair, flag variety, spherical action.

Introduction

Let $G$ be a connected reductive algebraic group over $\mathbb{C}$. Recently, there appear many interesting examples of product of (partial) flag varieties which have finitely many $G$-orbits. One example is $X = G/B \times G/B \times P(V)$ where $G = GL(V)$, $B$ a Borel subgroup and $P(V)$ denotes the projective space over $V$. The third factor $P(V)$ is isomorphic to a partial flag variety $G/P$, where $P$ is a maximal parabolic subgroup stabilizing a one dimensional subspace of $V$. It is known that there are finitely many $G$-orbits on $X$, and by the work of Travkin, Finkelberg and Ginzburg ([Tra09, FGT09]), there are miraculous similarities between $X$ and

Nishiyama and Ochiai

Steinberg variety. For example, they established a kind of Robinson-Schensted-Knuth correspondence for the orbits on $X$, and study some micro-local properties using Hecke algebras. The maximal parabolic $P$ above is called “mirabolic” after Ginzburg.

In general, one can consider a triple product of partial flag varieties. For a parabolic subgroup $P$ of $G$, we denote $X_P = G/P$ a partial flag variety. Magyar-Weymann-Zelevinsky ([MWZ99, MWZ00]) classified the triple flag varieties $X_{P_1} \times X_{P_2} \times X_{P_3}$ which have finitely many $G$-orbits when $G$ is a classical group of type $A$ or type $C$. They also gave parametrizations of orbits.

In this paper, we generalize the notion of triple flag varieties to a symmetric pair $(G, K)$, where $K$ is a symmetric subgroup of $G$ consisting of the fixed points of an involutive automorphism $\theta$. Thus we take parabolic subgroups $P \subset G$ and $Q \subset K$, and consider a product of partial flag varieties $X_P = G/P$ and $Z_Q = K/Q$. The group $K$ acts on the double flag variety $X_P \times Z_Q$ diagonally.

If one considers $G = G \times G$ and an involution $\theta: (g_1, g_2) = (g_2, g_1)$ of $G$, the symmetric subgroup $K = G^\theta$ is just the diagonal subgroup $\Delta(G) \subset G$. Then, for parabolic subgroups $P = (P^1, P^2) \subset G$ and $Q = \Delta(P^3) \subset K$, the double flag variety can be interpreted as

$$G/P \times K/Q = (G \times G)/(P^1 \times P^2) \Delta(G)/\Delta(P^3) \simeq X_{P^1} \times X_{P^2} \times X_{P^3}$$

which is nothing but the triple flag variety. So our double flag variety is a generalization of triple flag varieties.

We say a double flag variety $X_P \times Z_Q$ is of finite type if there are only finitely many $K$-orbits on it. One of the most interesting problems is to classify the double flag varieties of finite type. We give two efficient criterions for the finiteness of orbits using triple flag varieties. Namely, in Theorem 3.1, we prove

**Theorem 1.** Let $P'$ be a $\theta$-stable parabolic of $G$ such that $P' \cap K = Q$. If the number of $G$-orbits on $X_P \times X_{B(P)} \times X_{P'}$ is finite, then there are only finitely many $K$-orbits on the double flag variety $X_P \times Z_Q$.

The next theorem (Theorem 3.4) is also useful.

**Theorem 2.** Let $P^i$ ($i = 1, 2, 3$) be a parabolic subgroup of $G$. Suppose that $X_{P^1} \times X_{P^2} \times X_{P^3}$ has finitely many $G$-orbits and that $Q := P^2 \cap P^3$ is a parabolic subgroup of $K$. Then $X_{P^1} \times Z_Q$ has finitely many $K$-orbits.

Moreover, if $P^1$ is a Borel subgroup $B$ and the product $P_2 P_3$ is open in $G$, then the converse is also true, i.e., the double flag variety $X_B \times Z_Q$ is of finite type if and only if the triple flag variety $X_B \times X_{P^2} \times X_{P^3}$ is of finite type.

We construct many examples of double flag varieties of finite type using Theorems 1 and 2 in §§ 6–7, and if $P = B$ is Borel, we give complete classification for certain cases. However, in general cases, the classification of double flag varieties of finite type seems to be difficult.

Double flag varieties of finite type are strongly related to spherical actions of $G$ or $K$. Recall that an action of a reductive algebraic group $G$ on a variety $X$
is called spherical if there is an open dense $B$-orbit for a certain Borel subgroup $B$ of $G$. The existence of an open dense $B$-orbit is in fact equivalent to the finiteness of $B$-orbits on $X$ due to Brion [Bri89, § 1.5] and independently to Vinberg [Vin86]. We often use this finiteness criterion for spherical actions below.

The following theorem (Theorem 5.2), which is a corollary of the first theorem, exhibits a good connection to the spherical action.

**Theorem 3.** Let $P$ be a parabolic subgroup of $G$. If $X_P \times X_{\theta(P)}$ is a spherical $G$-variety, then $X_P$ is a spherical $K$-variety.

For a parabolic subgroup $P$ in $G$, we can find a finite-dimensional irreducible representation $V_\lambda$ of $G$ with highest weight $\lambda$ such that

$P = \{ g \in G \mid gv_\lambda \in \mathbb{C} v_\lambda \},$ where $v_\lambda$

denotes a highest weight vector of $V_\lambda$. Assume that the conclusion of Theorem 3 holds, i.e., we assume that $X_P$ is $K$-spherical. Then the contragredient $V_\lambda^{*}\big|_K$ decomposes multiplicity freely as a $K$-module for any non-negative integer $k \geq 0$ (see Lemma 5.3). This is one of interesting conclusions of Theorem 3.

We will also give some other examples of spherical multiple flag varieties in § 5.

There seems to be intimate connection between double flag varieties of finite type and visible actions (see [Kob05] for the definition of visible actions). Let us denote the compact real form of $K$ by $K_U$. Then $K_U$ acts on $X_P = G/P$ visibly if and only if $X_P$ is $K$-spherical. This is equivalent to say that $X_P \times Z_S$ is of finite type for a Borel subgroup $S$ of $K$. See also [Kob05, Cor. 17] and [Kob08].

**Acknowledgment.** We started the study of double flag varieties when we visited NCTS in National Cheng-Kung University in Tainan. We thank Ngau Lam for his generous hospitality at NCTS. We also thank Peter Trapa for useful discussion.

Finally, we thank the anonymous referee, who carefully read the earlier version of the paper. The references [Vin86] and [Krä76] are due to him/her. Also referee’s opinions have considerably improved the whole organization of the paper.

1. **Double flag varieties for symmetric pair**

Let $G$ be a connected reductive algebraic group over the complex number field $\mathbb{C}$, and $\theta$ its (non-trivial) involutive automorphism. We put $K = G^\theta$, a subgroup whose elements are fixed by $\theta$, and call it a symmetric subgroup of $G$. We denote the Lie algebra of $G$ (respectively of $K$) by $\mathfrak{g}$ (respectively $\mathfrak{k}$). In the following, we use the similar notation; for an algebraic group we use a Roman capital letter, and for its Lie algebra the corresponding German small letter.

For a parabolic subgroup $P$, we denote a partial flag variety consisting of all $G$-conjugates of $P$ by $X_P$. Since $P$ is self-normalizing, $X_P$ is isomorphic to $G/P$ as a $G$-variety. We also choose a $\theta$-stable parabolic $P'$ in $G$, and put $Q = K \cap P'$. Then $Q$ is a parabolic subgroup of $K$, and every parabolic subgroup of $K$ can be obtained in this way (see [BH00, Theorem 2]). We denote a partial flag variety $K/Q$ by $Z_Q$.

We consider the following problem.
Problem 1.1. Let the symmetric subgroup $K$ act on the product of the partial flag varieties $X_P \times Z_Q$ diagonally.

1. Classify all the pair $(P, Q)$ (or $(P, P')$) for a given pair $(G, K)$ which admits finitely many $K$-orbits on $X_P \times Z_Q$. We are also interested in the case where $X_P \times Z_Q$ contains an open $K$-orbit.

2. If there are finitely many orbits, classify all the $K$-orbits on $X_P \times Z_Q$, and study the geometry of orbits; for example, closure relations, combinatorial descriptions, equivariant cohomology and so on.

3. Establish a relation to the representation theory of Harish-Chandra $(g, K)$-modules.

All these problems are still open, but at the same time many (explicit) results are already known. We will give partial answers to the problem (1), which are new, in the following sections.

The problem (3) may require some account. Let us explain it briefly. Since we assume $P'$ is a $\theta$-stable parabolic subgroup and $Q = K \cap P'$, $Z_Q = K/Q$ can be embedded into $X_{P'} = G/P'$, which is a partial flag variety of $G$. In fact, $Z_Q$ is isomorphic to a closed $K$-orbit in $X_{P'}$, and for every closed $K$-orbit in $X_{P'}$, one can attach a Harish-Chandra $(g, K)$-module via Beilinson-Bernstein theory. This module is known to be a derived functor module $\mathcal{A}_{p'}(\rho')$ induced from a one-dimensional character of a $\theta$-stable parabolic subalgebra $p'$ contained in the $K$-orbit. On the other hand, there is an open dense $K$-orbit on $X_P$ which should correspond to a degenerate principal series representation if some translate of $p$ has a real form. Thus, in a suitable space of cohomology of an invertible sheaf over $X_P \times Z_Q$, one can hopefully realize the tensor product of a degenerate principal series representation and $\mathcal{A}_{p'}(\rho')$. Our condition of the finiteness of the $K$-orbits put a restriction on the tensor product and we expect a kind of multiplicity-free property on the tensor product.

2. Triple flags

Let us return to Problem 1.1 and consider a symmetric pair $(G, \mathbb{K})$, where $G = G \times G$ for a reductive group $G$ over $\mathbb{C}$ and $\mathbb{K} = \Delta G$ is the diagonal embedding. This symmetric subgroup $\mathbb{K}$ corresponds to the involution $\theta : G \to G$ defined by $\theta(g_1, g_2) = (g_2, g_1)$. Take a parabolic subgroup $P = P_1 \times P_2$ in $G$, where $P_i$ is a parabolic subgroup of $G$. A $\theta$-stable parabolic subgroup $P'$ in $G$ can be written as $P' = P_3 \times P_3$ for a certain parabolic subgroup $P_3$ in $G$. Thus $Q = \mathbb{K} \cap P' = \Delta P_3$ is a diagonal subgroup in $\Delta G$. Now it is immediate to see that, in this setting, our Problem 1.1 can be translated into

Problem 2.1. Let $G$ act on the triple product of partial flag varieties $X_{P_1} \times X_{P_2} \times X_{P_3}$ diagonally.

1. Classify all the triples $(P_1, P_2, P_3)$, for which there are finitely many $G$-orbits on the triple product $X_{P_1} \times X_{P_2} \times X_{P_3}$. If this is the case, we say the triple product is of finite type.

2. If there are finite number of orbits, classify all the $G$-orbits and study the
Establish a relation to the representation theory. This problem (at least for (1) and (2)) was solved almost completely for classical groups by Magyar-Weymann-Zelevinsky ([MWZ99, MWZ00]), Travkin ([Tra09]) and Finkelberg-Ginzburg-Travkin ([FGT09]). If \( P^3 \) is a Borel subgroup, Littelmann ([Lit94]) investigated a representation theoretic meaning; in fact, it seems that this work is one of motivations of [MWZ99, MWZ00]. We do not go into the details of their works, but let us introduce the classification achieved by [MWZ99, MWZ00] without proof since we need it later.

### 2.1. Type A.

Let \( G = \text{GL}_n(\mathbb{C}) \) be the general linear group, which we will denote simply by \( \text{GL}_n \) if there is no confusion. To specify a parabolic subgroup \( P \) of \( G \), we use an unordered partition (or composition) \( \lambda \) of \( n \); i.e., if \( P = P_\lambda \) corresponds to \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_l) \), its Levi part is in block diagonal form of \( \text{GL}_{\lambda_1} \times \text{GL}_{\lambda_2} \times \cdots \times \text{GL}_{\lambda_l} \), and its unipotent radical is in upper triangular form. The number of non-zero parts in \( \lambda \) is denoted by \( \ell(\lambda) \) and is called the length of \( \lambda \).

**Theorem 2.2** (Magyar-Weymann-Zelevinsky). Let \( X = G/P \) be a partial flag variety, where \( G = \text{GL}_n \).

1. For a collection of proper parabolic subgroups \( P_1, \ldots, P_k \), if the number of \( G \)-orbits on \( X_{P_1} \times X_{P_2} \times \cdots \times X_{P_k} \) is finite, then \( k \leq 3 \).
2. A triple product \( X_{P_\lambda} \times X_{P_\mu} \times X_{P_\nu} \) of partial flag varieties is of finite type if and only if it is from the following list (with possible change of the order of parabolic subgroups, and the order of parts of partitions involved).

<table>
<thead>
<tr>
<th>type ( S_{q,r} )</th>
<th>( (\ell(\lambda), \ell(\mu), \ell(\nu)) )</th>
<th>extra condition(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>( D_{r+2} )</td>
<td>( (2, 2, 2) )</td>
<td>( n = 2 )</td>
</tr>
<tr>
<td>( E_6 )</td>
<td>( (2, 3, 3) )</td>
<td>( n = 4 )</td>
</tr>
<tr>
<td>( E_7 )</td>
<td>( (2, 3, 4) )</td>
<td>( n = 5 )</td>
</tr>
<tr>
<td>( E_8 )</td>
<td>( (2, 3, 5) )</td>
<td>( n = 6 )</td>
</tr>
<tr>
<td>( E_r^{(a)} )</td>
<td>( (2, 3, r) )</td>
<td>( \lambda = (n - 2, 2) \</td>
</tr>
<tr>
<td>( E_r^{(b)} )</td>
<td>( (2, 3, r) )</td>
<td>( \mu = (\mu_1, \mu_2, 1) )</td>
</tr>
</tbody>
</table>

For the first statement, note that if \( k = 1 \) then \( X_P \) is homogeneous; if \( k = 2 \), then \( G \setminus (X_{P_1} \times X_{P_2}) \simeq P^1 \setminus G/P^2 \), which is further isomorphic to \( W_{P_1} \setminus W/W_{P_2} \) by the Bruhat decomposition (we denote by \( W \) the Weyl group of \( G \), and by \( W_P \) the Weyl group of \( P \)). So they are always of finite type.

### 2.2. Type C.

In this subsection we put \( G = \text{Sp}_{2n}(\mathbb{C}) \), which we abbreviate to \( \text{Sp}_{2n} \). The symplectic group \( G \) acts on partial flags of isotropic subspaces \( F_1 \subset F_2 \subset \cdots \subset F_l \) of fixed dimensions. Let us denote the orthogonal subspace of \( F_i \) by \( F_i^\perp \). Then we have a partial flag of subspaces

\[
F_1 \subset F_2 \subset \cdots \subset F_{l-1} \subset F_l \subset F_l^\perp \subset F_{l-1}^\perp \subset \cdots \subset F_2^\perp \subset F_1^\perp.
\]
A parabolic subgroup of $G$ is specified as a fixed point subgroup of a partial flag as in (1), and its conjugacy class is determined by the dimensions of the subspaces in the flag. We put, if $\dim F_l < n$, then

$$
\begin{align*}
\lambda_i &= \dim F_i/F_{i-1} \\
\lambda_{i+1} &= \dim F^\perp_{i}/F_i = 2(n - \dim F_i) \\
\lambda_{i+i+1} &= \dim F^\perp_{i-i+1}/F_{i-i+1} = \lambda_{i-i+1} 
\end{align*}
$$

with $F_0$ understood as $\{0\}$, and if $\dim F_l = n$

$$
\begin{align*}
\lambda_i &= \dim F_i/F_{i-1} \\
\lambda_{i+1} &= \dim F^\perp_{i-i+1}/F_{i-i+1} = \lambda_{i-i+1} 
\end{align*}
$$

Then $\lambda = (\lambda_1, \lambda_2, \ldots)$ is an unordered partition with $|\lambda| = 2n$, where $|\lambda|$ is the size of $\lambda$. We denote by $P = P_\lambda$ the corresponding parabolic subgroup, whose Levi part is isomorphic to $\text{GL}_{\lambda_1} \times \cdots \times \text{GL}_{\lambda_l} \times \text{Sp}_{\lambda_{l+1}}$. Here the factor $\text{Sp}_{\lambda_{l+1}}$ does not appear if $\dim F_l = n$. Thus, if $\lambda = (n, n)$, the corresponding parabolic subgroup $P_{(n, n)}$ is a Siegel parabolic with Levi component $\text{GL}_n$; and if $\lambda = (m, 2(n - m), m)$ with $m < n$, then $P_{(m, 2(n-m), m)}$ is a maximal parabolic subgroup with Levi component $\text{GL}_m \times \text{Sp}_{2(n-m)}$.

With this notation, we can state the following

**Theorem 2.3** (Magyar-Weymann-Zelevinsky). Let $X_P = G/P$ be a partial flag variety, where $G = \text{Sp}_{2n}$.

1. For a collection of proper parabolic subgroups $P^1, \ldots, P^k$, if the number of $G$-orbits on $X_{P^1} \times X_{P^2} \times \cdots \times X_{P^k}$ is finite, then $k \leq 3$.

2. A triple product $X_{P_\lambda} \times X_{P_\mu} \times X_{P_\nu}$ of partial flag varieties is of finite type if and only if it is from the following list (up to appropriate changes of the order of parabolic subgroups, and the order of parts of partitions involved).

<table>
<thead>
<tr>
<th>type</th>
<th>$(\ell(\lambda), \ell(\mu), \ell(\nu))$</th>
<th>extra condition(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{Sp} E_{r+2}$</td>
<td>(2, 2, $r$)</td>
<td>$\lambda = \mu = (n, n)$</td>
</tr>
<tr>
<td>$\text{Sp} E_6$</td>
<td>(2, 3, 3)</td>
<td>$\lambda = (n, n)$</td>
</tr>
<tr>
<td>$\text{Sp} E_7$</td>
<td>(2, 3, 4)</td>
<td>$\lambda = (n, n)$</td>
</tr>
<tr>
<td>$\text{Sp} E_8$</td>
<td>(2, 3, 5)</td>
<td>$\lambda = (n, n)$</td>
</tr>
<tr>
<td>$\text{Sp} E_{r+3}^{(b)}$</td>
<td>(2, 3, $r$)</td>
<td>$\lambda = (n, n)$; $\mu = (1, 2n - 2, 1)$; $3 \leq r$</td>
</tr>
<tr>
<td>$\text{Sp} Y_{4,r}$</td>
<td>(3, 3, $r$)</td>
<td>$\lambda = \mu = (1, 2n - 2, 1)$; $3 \leq r$</td>
</tr>
</tbody>
</table>

Here $\ell(\lambda)$ denotes the length of $\lambda$. So, if $\ell(\lambda) = 2$, it implies $\lambda = (n, n)$ and $P_\lambda$ is a Siegel parabolic. If $\ell(\lambda) = 3$, then $P_\lambda$ is a maximal parabolic as explained above.

Note that in the case of type C, two of the parabolic subgroups among three should be maximal. Moreover, one of those maximal parabolic subgroups must be a Siegel parabolic $P_{(n, n)}$ or $P_{(1, 2n-2, 1)}$ with Levi component $\mathbb{C}^\times \times \text{Sp}_{2n-2}$. 

3. Double flag varieties of finite type

Now we return to our original setting, i.e., \( G \) is a reductive group with an involution \( \theta \), and \( K = G^\theta \) a symmetric subgroup, which is automatically reductive. We take a parabolic subgroup \( P \) and a \( \theta \)-stable parabolic subgroup \( P' \) in \( G \), and put \( Q = P' \cap K \), which is a parabolic subgroup of \( K \). As we have already mentioned, for any parabolic \( Q \subset K \), we can choose a \( \theta \)-stable parabolic subgroup \( P' \) in \( G \) which cuts out \( Q \) from \( K \). So our assumption causes no essential restriction.

Let us consider the diagonal action of \( K \) on the product of partial flag varieties \( X_P \times Z_Q \), where \( X_P = G/P \) and \( Z_Q = K/Q \). We also put \( X_P^\theta = X_{\theta(P)} = G/\theta(P) \).

The following is one of our main results in this article.

**Theorem 3.1.** If the number of \( G \)-orbits on \( X_P \times X_P^\theta \times X_P \) is finite, then there are only finitely many \( K \)-orbits on the double flag variety \( X_P \times Z_Q \).

**Proof.** If \( P' = G \), then this theorem reduces to the well-known fact that there are finitely many \( K \)-orbits on the partial flag variety \( X_P \) ([Mat79, Mat82], [Ros79], [Spr85]). For this, there is a beautiful proof by Miličić [Mil93, §H.2, Theorem 1], and our proof is an extension of his idea to the case of double flags.

Let us consider the following \( \theta \)-twisted diagonal embedding:

\[
\Delta_\theta : X_P \ni P^1 \mapsto (P^1, \theta(P^1)) \in X_P \times X_P^\theta,
\]

where we identify \( X_P \) with the set of parabolic subgroups of \( G \) which are conjugate to \( P \). Note that \( \theta(P^1) \) belongs to \( X_P^\theta \) for any \( P^1 \in X_P \). Thus we can embed

\[
X_P \times Z_Q \xrightarrow{\sim} \Delta_\theta(X_P) \times Z_Q \hookrightarrow \Delta_\theta(X_P) \times \Delta_\theta(X_P^\theta) \times X_P^\theta \times X_P \times X_P^\theta \times X_P'
\]

This is a closed embedding, and clearly \( K \)-equivariant. Let us consider a \( \theta \)-twisted action of \( G \) on \( X_P \times X_P^\theta \times X_P' \):

\[
g(P^1, P^2, P^3) = (g \cdot P^1, \theta(g) \cdot P^2, g \cdot P^3) \quad (g \in G; \quad (P^1, P^2, P^3) \in X_P \times X_P^\theta \times X_P')
\]

which preserves \( \Delta_\theta(X_P) \times X_P' \). Note that \( g \in G \) acts on \( X_P \) by conjugation \( g \cdot P^1 = g P^1 g^{-1} \). If we indicate this action also by \( \Delta_\theta \), there are only finitely many \( \Delta_\theta(G) \)-orbits on \( \Delta_\theta(X_P) \times X_P' \), namely we have

\[
\Delta_\theta(G) \backslash \Delta_\theta(X_P) \times X_P' \simeq \Delta_\theta(X_P) \times X_P' \simeq W_P \backslash W/W_P,
\]

where the last isomorphism comes from the Bruhat decomposition (see §2). So pick a \( \Delta_\theta(G) \)-orbit \( O_w^\theta \) in \( \Delta_\theta(X_P) \times X_P' \) indexed by \( w \in W_P \backslash W/W_P \).

**Lemma 3.2.** Take any \( G \)-orbit \( O \) in \( X_P \times X_P^\theta \times X_P' \), and put \( X = \Delta_\theta(X_P) \times Z_Q \).

- (1) There are finitely many \( K \)-orbits in \( O \cap O_w^\theta \cap X \).
- (2) Let us write the \( K \)-orbit decomposition as \( O \cap O_w^\theta \cap X = \bigsqcup_{i=1}^r O_i \). Then each orbit \( O_i \) is a connected component of \( O \cap O_w^\theta \cap X \), which is also an irreducible component as an algebraic variety.
Let us assume the above lemma. Since the decomposition

\[ X = \bigsqcup_{w \in W' \setminus W/W'} O_w^\theta \cap X \]

is finite, and there are only finitely many possibilities of \( G \)-orbits \( O \) in \( X_P \times X_P' \) by the assumption of the theorem, we can conclude that \( \#K \setminus X = \#K \setminus (X_P \times Z_Q) < \infty \).

Thus it is sufficient to prove the lemma.

Pick a point

\[ \xi = (P^1, \theta(P^1), P^3) \in O \cap O_w^\theta \cap X \subset X_P \times X_P' \]

and consider \( O = K \cdot \xi \), a \( K \)-orbit through \( \xi \). The tangent space of \( O \) at \( \xi \) is contained in

\[ T_\xi O \subset T_\xi (O \cap O_w^\theta \cap X) \subset T_\xi O \cap T_\xi O_w^\theta \cap T_\xi X. \tag{3} \]

We know

\[ T_\xi O = \{(y + p_1, y + \theta(p_1), y + p'_3) \mid y \in g\}, \]
\[ T_\xi O_w^\theta = \{(x + p_1, \theta(x) + \theta(p_1), x + p'_3) \mid x \in g\}. \]

We denote a Cartan decomposition by \( g = k \oplus s \), where \( s \) is the \((-1)\)-eigenspace of the involution \( \theta \) on \( g \). Let us prove that

\[ T_\xi O \cap T_\xi O_w^\theta \subset \{(z + p_1, z + \theta(p_1), z + s + p'_3) \mid z \in k\}. \tag{4} \]

To deduce this containment, take a vector from the left hand side. Then it is expressed as

\[ (y + p_1, y + \theta(p_1), y + p'_3) = (x + p_1, \theta(x) + \theta(p_1), x + p'_3) \]

for some \( x \in g \) and \( y \in g \). From this, we get

\[ x - y \in p_1, \quad \theta(x) - y \in \theta(p_1), \quad \text{and} \quad x - y \in p'_3. \]

By the second formula, we know \( x - \theta(y) \in p_1 \), and thus \( y - \theta(y) \in p_1 \cap \theta(p_1) \).

Let us decompose \( y \) along the Cartan decomposition:

\[ y = \frac{1}{2}(y + \theta(y)) + \frac{1}{2}(y - \theta(y)) =: z + v \in k \oplus s. \]

Then we know \( v \in p_1 \cap \theta(p_1) \) and

\[ (y + p_1, y + \theta(p_1), y + p'_3) = (z + p_1, z + \theta(p_1), z + v + p'_3) \quad (v \in s), \]

which proves (4).

From (4), we get

\[ T_\xi O \cap T_\xi O_w^\theta \cap T_\xi X \subset \{(z + p_1, z + \theta(p_1), z + p'_3) \mid z \in k\} = T_\xi O. \tag{5} \]
To see this, we concentrate on the third component of $T_\xi X$, which must be of the form $z' + p'_3$ for some $z' \in \mathfrak{k}$. Equating this with the third component $z + v + p'_3$ of $T_\xi \mathcal{O} \cap T_\xi \mathcal{O}_w^\theta$, we get

$$(z - z') + v \in p'_3 \quad (z, z' \in \mathfrak{k}; \ v \in \mathfrak{s}).$$

Since $p'_3$ is $\theta$-stable, we get $z - z' \in \mathfrak{k} \cap p'_3$ and $v \in \mathfrak{s} \cap p'_3$. Therefore, the third component becomes $z + v + p'_3 = z + p'_3$.

By Equations (3) and (5), we have $T_\xi \mathcal{O} \subset T_\xi (\mathcal{O} \cap \mathcal{O}_w^\theta \cap X) \subset T_\xi \mathcal{O} \cap T_\xi \mathcal{O}_w^\theta \cap T_\xi X \subset T_\xi \mathcal{O}$,

and conclude that all the containments in the above formula are in fact equalities. This means that $\mathcal{O}$ is an open neighborhood of $\xi \in \mathcal{O} \cap \mathcal{O}_w^\theta \cap X$. Since $\xi$ is arbitrary, $\mathcal{O} \cap \mathcal{O}_w^\theta \cap X$ is smooth and its irreducible components coincide with connected components. Since the number of irreducible components of an algebraic variety is finite, we conclude that there are only finitely many $K$-orbits in $\mathcal{O} \cap \mathcal{O}_w^\theta \cap X$.

Thus we finished the proof of Theorem 3.1.

The above theorem is strong enough to produce many interesting examples of double flag varieties of finite type. However, it also misses many possibilities. Here we introduce another kind of technique, which can present some more examples. A key idea is that a homogeneous space $G/Q$ sometimes can be embedded into a product of (partial) flag varieties. It is an equivariant compactification, and is considered to be a generalization of a complexification of the Harish-Chandra embedding of a symmetric space into the product of the flag varieties.

First, let us explain the classical Harish-Chandra embedding.

Let us assume that $K$ is an intersection of a parabolic subgroup $P$ of $G$ and its opposite $P^\circ$. Thus $K = P \cap P^\circ$ is a Levi component of $P$. Then $G/K$ can be embedded into $\mathfrak{x}_P \times \mathfrak{x}_{P^\circ}$:

$$G/K \ni gK \mapsto (gP, gP^\circ) \in \mathfrak{x}_P \times \mathfrak{x}_{P^\circ},$$

and this embedding is an open embedding (compare their dimension). Let us fix a Borel subgroup $B \subset G$, and consider an embedding

$$B \backslash G/K \hookrightarrow B \backslash (\mathfrak{x}_P \times \mathfrak{x}_{P^\circ}) \cong G \backslash (\mathfrak{x}_B \times \mathfrak{x}_P \times \mathfrak{x}_{P^\circ}).$$

Since $\#B \backslash G/K < \infty$, there is an open $B$-orbit, hence $\mathfrak{x}_P \times \mathfrak{x}_{P^\circ}$ is a spherical $G$-variety. (See § 5 for fundamental properties of spherical varieties.) Therefore there are finite number of $B$-orbits on $\mathfrak{x}_P \times \mathfrak{x}_{P^\circ}$, which is equivalent to the finiteness of $G$-orbits in $\mathfrak{x}_B \times \mathfrak{x}_P \times \mathfrak{x}_{P^\circ}$.

Thus we proved the following

**Proposition 3.3.** Assume that a Levi component of a parabolic subgroup $P$ is a symmetric subgroup of $G$. Then $\mathfrak{x}_B \times \mathfrak{x}_P \times \mathfrak{x}_{P^\circ}$ contains finitely many $G$-orbits, where $P^\circ$ denotes a parabolic subgroup opposite to $P$. 
The assumption of the proposition above is satisfied for a symmetric pair $(G, K)$ which is the complexification of a Hermitian symmetric pair $(G_\mathbb{R}, K_\mathbb{R})$. If $P$ has an abelian unipotent radical, then $K = P \cap P^\circ$ satisfies this assumption (i.e., $(G, K)$ is a symmetric pair; see [RRS92]).

Now we generalize the above situation to get a simple criterion of finiteness of $K$-orbits on the double flag variety.

**Theorem 3.4.** Let $P_i^i$ ($i = 1, 2, 3$) be a parabolic subgroup of $G$. Suppose that $X_{p_i} \times X_{p_2} \times X_{p_3}$ has finitely many $G$-orbits and that $Q := P^2 \cap P^3$ is a parabolic subgroup of $K$. Then $X_{p_1} \times \mathbb{Z}_Q$ has finitely many $K$-orbits.

Moreover, if $P^1$ is a Borel subgroup $B$ and the product $P_2P_3$ is open in $G$, then the converse is also true, i.e., the double flag variety $X_B \times \mathbb{Z}_Q$ is of finite type if and only if the triple flag variety $X_B \times X_{p_2} \times X_{p_3}$ is of finite type.

**Proof.** We have a $G$-equivariant diagonal embedding $G/Q \hookrightarrow X_{p_2} \times X_{p_3}$ by $gQ \mapsto (gP^2, gP^3)$. Then we have the following natural inclusion

$$K\backslash(X_{p_1} \times \mathbb{Z}_Q) \cong P^1\backslash G/Q = G\backslash(X_{p_1} \times G/Q) \hookrightarrow G\backslash(X_{p_1} \times X_{p_2} \times X_{p_3}),$$

which proves the first claim.

Let us assume that $P^1 = B$ is a Borel subgroup and $P_2P_3 \subset G$ is open. To prove the converse, let us assume that $X_B \times \mathbb{Z}_Q$ is of finite type. Since $K\backslash X_B \times \mathbb{Z}_Q \cong B\backslash G/Q$, there is an open $B$-orbit on $G/Q$. Since $P_2P_3$ is open in $G$, the map $G/Q \hookrightarrow X_{p_2} \times X_{p_3}$ above is an open embedding, and consequently there is an open $B$-orbit on $X_{p_2} \times X_{p_3}$. Thus $X_{p_2} \times X_{p_3}$ is a spherical $G$-variety, hence there are only finitely many $B$-orbits on it. Now, since $G\backslash(X_B \times X_{p_2} \times X_{p_3}) \cong B\backslash(X_{p_2} \times X_{p_3})$, we are done. \endproof

Note that $(P^1, P^2, P^3) = (B, P, P^\circ)$ and $Q = P \cap P^\circ = K$ in Proposition 3.3 above.

4. Richardson-Springer theory

We use the same notation as in the former section. If $P' = G$ and $P = B$, Theorem 3.1 reduces to the one which claims that $K\backslash G/B$ is a finite set. Let us compare this to the classification of $K$-orbits on $X_B = G/B$ by Richardson-Springer.

4.1. Review of Richardson-Springer Theory.

First, we briefly review the theory of Richardson and Springer [RS90, RS93]. We fix a $\theta$-stable Borel subgroup $B$ and a $\theta$-stable maximal torus $T \subset B$. Such pair always exists ([Ste68, Theorem 7.5]). Let $T$ be the set of maximal tori in $G$, and $T^\theta$ the set of $\theta$-stable maximal tori. As before $X_B$ denotes the set of all Borel subgroups in $G$. We put $C = \{(T_1, B_1) \in T \times X_B \mid T_1 \subset B_1\}$. Then there are natural projections $p_1 : C \rightarrow T$ and $p_2 : C \rightarrow X_B$.

The projection $p_2 : C \rightarrow X_B$ gives $C$ the structure of fiber bundle over $X_B$ with the fiber $B_1/T_1$. The projection $p_1 : C \rightarrow T$ is a Galois covering map with the Galois group $W = W_G(T_1)$. Both of them tell us that $C$ is isomorphic to $G/T$:

$$C \simeq G \times_B (B/T) \simeq G \times_{N_G(T)} (N_G(T)/T) \simeq G/T.$$
There is a bijection

\[ C^\theta := \{(T_1, B_1) \in T^\theta \times X_B \mid T_1 \subset B_1\} = C \cap (T^\theta \times X_B). \]

**Theorem 4.1** (Richardson-Springer). The $K$-equivariant projection $p_2 : C^\theta \to X_B$ induces a bijection $K \setminus C^\theta \sim K \setminus X_B$.

**Corollary 4.2.** Let us fix representatives $\{T_i\}$ in the $K$-conjugacy classes of the $\theta$-stable maximal tori $K \setminus T^\theta$. For each representative $T_1$, we also fix a Borel subgroup $B_1$ which contains $T_1$. Then there is a bijection

\[ \prod_{T_1 \in K \setminus T^\theta} W_K(T_1) \setminus W_G(T_1) \sim K \setminus X_B, \quad W_K(T_1) w \mapsto K \cdot (wB_1w^{-1}), \]

where $W_H(T_1) = N_H(T_1)/Z_H(T_1)$ is a Weyl group with representatives in $H \subset G$.

The incidence variety $C^\theta$ is sometimes too big for our purpose. We can take a smaller subvariety as follows. Define a map $\tau : G \to G$ by $\tau(g) = g^{-1}\theta(g)$ ($g \in G$). We denote by $\Xi = \text{Im } \tau$ the image of the map, which is known to be closed in $G$ ([Ric82]). Since $\tau$ is clearly invariant under the left translation by $K$, it induces a map $\Psi : K \setminus G \to \Xi$. By [Ric82, Lemma 2.4], $\Psi$ is an isomorphism from the symmetric variety $K \setminus G$ to the closed subvariety $\Xi \subset G$.

Recall the fixed $\theta$-stable maximal torus $T$. We define

\[ \mathcal{V} := \tau^{-1}(N_G(T)) = \{g \in G \mid g^{-1}\theta(g) \text{ normalizes } T\}, \]

on which $K$ acts on the left and $T$ acts on the right.

**Theorem 4.3** (Richardson-Springer). There is a bijection $K \setminus \mathcal{V} / T \sim K \setminus X_B$, which is induced by $\mathcal{V} \ni g \mapsto g \cdot B \in X_B$.

Let us briefly explain that this is an immediate consequence of Theorem 4.1. An element $(T_1, B_1) \in C^\theta$ is expressed as $(T_1, B_1) = (gTg^{-1}, gBg^{-1})$ for some $g \in G$. The representative $g \in G$ is determined up to the right multiplication of $T$. Since $T_1 = gTg^{-1}$ is $\theta$-stable, we have

\[ gTg^{-1} \sim \theta(gTg^{-1}) = \theta(g) T \theta(g^{-1}). \]

Hence $g^{-1}\theta(g) \in N_G(T)$. Thus $\mathcal{V} / T$ corresponds to $C^\theta$ naturally by $\mathcal{V} \ni g \mapsto (g \cdot T, g \cdot B) \in C^\theta$. So $K$-orbits in $\mathcal{V} / T$ are in bijection with $K$-orbits in $C^\theta$, which are in turn bijective to $K \setminus X_B$.

Now we get a map

\[ K \setminus X_B \sim K \setminus \mathcal{V} / T \xrightarrow{T} N_G(T) \to W = N_G(T)/T, \]

which sends $KgB$ to $w = g^{-1}\theta(g)$ in $W$. Note that $\theta(w) = \theta(g)^{-1}g = w^{-1}$. We call $v \in W$ a twisted involution if $\theta(v) = v^{-1}$ holds, and put $\mathcal{I} = \{v \in W \mid \theta(v) = v^{-1}\}$, the set of twisted involutions. With this notation, we finally get a map

\[ \phi : K \setminus X_B \to \mathcal{I} \subset W; \quad (7) \]
which we call the Richardson-Springer map.

4.2. Geometry of Richardson-Springer map.

Let us recall the notation in §3. We take $P = B$, a Borel subgroup, and $P' = G$ so that $X_P \times Z_Q = X_B$.

We take a $G$-orbit $\mathcal{O}$ in $X_B \times X_B$ under the diagonal action. Since $G \setminus (X_B \times X_B) \simeq B \setminus G/B$, the $G$-orbits are classified by the Weyl group $W = W_G(T)$. So we write $\mathcal{O} = \mathcal{O}_w (w \in W)$. Let us consider the $\theta$-twisted embedding of $X_B$ into $X_B \times X_B$, i.e.,

$$\Delta_\theta : X_B \hookrightarrow X_B \times X_B, \quad B_1 \mapsto (B_1, \theta(B_1)).$$

We denote $X = \Delta_\theta(X_B)$. Then Lemma 3.2 tells us the following

**Lemma 4.4.** For each $w \in W$, the connected components of $\mathcal{O}_w \cap X$ are exactly the irreducible components. Each connected component is a $K$-orbit, hence there are finitely many $K$-orbits in $\mathcal{O}_w \cap X$.

Now pick a point $\xi$ in $\mathcal{O}_w \cap X$. Then $\xi = (B_1, \theta(B_1)) = (g \cdot B, (g\hat{w}) \cdot B)$, where $\hat{w} \in N_G(T)$ represents $w \in W = N_G(T)/T$.

$$B_1 = gBg^{-1}, \quad \theta(B_1) = (g\hat{w})B(g\hat{w})^{-1}, \quad (g\hat{w})^{-1}\theta(g) \in B$$

Thus we have $\hat{w}^{-1}g^{-1}\theta(g) \in B$. From Theorem 4.3, we can assume $g^{-1}\theta(g) \in N_G(T)$. Therefore $\hat{w}^{-1}g^{-1}\theta(g) \in B \cap N_G(T) = T$. Thus $g^{-1}\theta(g)$ represents $w$ also.

**Theorem 4.5.** Let us denote $X = \Delta_\theta(X_B) \subset X_B \times X_B$. For $w \in W$, let us consider a $G$-orbit $\mathcal{O}_w = G \cdot (B, w \cdot B) \in X_B \times X_B$. If $\mathcal{O}_w \cap X \neq \emptyset$, then $w \in \mathcal{I}$ is a twisted involution, i.e., it satisfies $w^{-1} = \theta(w)$. Moreover, if $w \in \mathcal{I}$, the connected components of $\mathcal{O}_w \cap X$ correspond bijectively to the $K$-orbits in $K \setminus X_B$ which are in the fiber $\phi^{-1}(w)$ of $w$ of the map $\phi$ (see Equation (7)).

This theorem gives a geometric interpretation of the Richardson-Springer map $\phi : K \setminus X_B \to \mathcal{I}$.

5. Spherical actions on multiple flag varieties

5.1. Spherical varieties.

The finiteness of $K$-orbits on the product of flag varieties and spherical actions of $G$ or $K$ are closely related.

Recall that a $G$-variety $X$ is called spherical if it has an open dense $B$-orbit, where $B$ is a Borel subgroup. Note that $X$ is $G$-spherical if and only if $\#B \setminus X < \infty$.

Let us begin with an easy but fundamental lemma.

**Lemma 5.1.** The following conditions are equivalent.
Let $B \times S$ be a Borel subgroup of $G \times K$. Then $K$ has finitely many orbits on $X_B \times Z_S$.

(2) $G \cong (G \times K)/\Delta K$ is $G \times K$-spherical.

(3) Every irreducible finite-dimensional rational representation of $G$ is decomposed into the representations of $K$ multiplicity freely.

**Proof.** Let us consider the condition (1). Since $X_B \times Z_S = (G \times K)/(B \times S)$, the finiteness of $K$-orbits on it implies the finiteness of $B \times S$-orbits on $K \backslash (G \times K)$. Since $B \times S$ is Borel in $G \times K$, this is equivalent to that $K \backslash (G \times K)$ is $(G \times K)$-spherical, which is the condition (2).

Note that $(G \times K)/K$ is affine. So, the existence of an open $B \times S$-orbit is equivalent to the condition that the regular function ring $\mathbb{C}[G \times K]^K$ decomposes multiplicity freely as a representation of $G \times K$. By the Frobenius reciprocity, we know

$$\mathbb{C}[G \times K]^K \simeq \bigoplus_{(\pi, \tau) \in \text{Irr}(G) \times \text{Irr}(K)} \text{Hom}_K(\pi, \tau) \otimes (\pi \boxtimes \tau^*)$$

where $\tau^*$ denotes the contragredient of $\tau$ and $\pi \boxtimes \tau^*$ means outer tensor product. Thus we get $\dim \text{Hom}_K(\pi, \tau) \leq 1$ for any $\pi \in \text{Irr}(G)$ and $\tau \in \text{Irr}(K)$, which is equivalent to the condition (3).

There are very few examples which satisfy the conditions in the above lemma, and they are completely classified by Krämer [Krä76]. Best known one might be the pair $(G, K) = (\text{GL}_n, \text{GL}_1 \times \text{GL}_{n-1})$, which is related to the multiplicity free branching rule (Pieri formula) and Gelfand-Zeitlin basis.

The following theorem is a direct consequence of Theorem 3.1.

**Theorem 5.2.** Let $P$ be a parabolic subgroup of $G$. If $X_P \times X_P^\theta$ is a spherical $G$-variety, then $X_P$ is a spherical $K$-variety.

**Proof.** Since $G \backslash (X_P \times X_P^\theta \times X_B) \simeq B \backslash (X_P \times X_P^\theta)$, the product $X_P \times X_P^\theta$ is a spherical $G$-variety if and only if there are finitely many $G$-orbits on $X_P \times X_P^\theta$. We can assume that $B$ is $\theta$-stable and $S := K \cap B$ is a Borel subgroup of $K$. Then, by Theorem 3.1, this implies that there are finitely many $K$-orbits on $X_P \times Z_S \simeq G/P \times K/S$. Since $K \backslash (G/P \times K/S) \simeq S\backslash G/P$, this is equivalent to say that $X_P \simeq G/P$ is $K$-spherical.

Let us take a $\theta$-stable Borel subgroup $B$ of $G$, and fix a positive root system $\Delta^+$ corresponding to $B$. We denote by $\Pi \subset \Delta^+$ a simple system. For a parabolic subgroup $P$ in $G$ which contains $B$, we can associate a subset $\Phi \subset \Pi$ so that $\Pi \setminus \Phi$ generates a sub root system for a Levi component of $P$. For $\alpha \in \Phi$, we denote a fundamental weight corresponding to $\alpha$ by $\omega_\alpha$. Put $\lambda = \sum_{\alpha \in \Phi} c_\alpha \omega_\alpha$ a linear combination of those fundamental weights with positive integer coefficients $c_\alpha$’s. We assume that $\lambda$ is integral for $G$. Let us denote by $V_\lambda$ a finite dimensional irreducible representation of $G$ with highest weight $\lambda$, and by $v_\lambda$ its highest weight vector. Then we have

$$P = \{ g \in G \mid g \cdot v_\lambda \in \mathbb{C}v_\lambda \}.$$
If we denote by \( \mathbb{P}(V) \) a projective space over \( V \) and \([v_{\lambda}]\) a point in \( \mathbb{P}(V) \) determined by the line through it, it is equivalent to say that \( G \cdot [v_{\lambda}] \simeq \mathfrak{X}_P \).

Let us denote \( \widehat{\mathfrak{X}}_P = \mathbb{C}v_{\lambda} \subset \mathcal{V}_P \), the affine cone over \( \mathfrak{X}_P \).

With these notations, we have the following

**Lemma 5.3.** The partial flag variety \( \mathfrak{X}_P \) is \( K \)-spherical if and only if \( V^*_{k\lambda}|_K \) decomposes multiplicity freely as a \( K \)-module for any non-negative integer \( k \geq 0 \).

**Proof.** The partial flag variety \( \mathfrak{X}_P \) is \( K \)-spherical if and only if the affine cone \( \widehat{\mathfrak{X}}_P \) is \( \mathbb{C}^\times \times K \)-spherical. Since \( \widehat{\mathfrak{X}}_P \) is an affine variety, it is \( \mathbb{C}^\times \times K \)-spherical if and only if the regular function ring \( \mathbb{C}[\widehat{\mathfrak{X}}_P] \) decomposes multiplicity freely. Note that

\[
\mathbb{C}[\widehat{\mathfrak{X}}_P] \simeq \bigoplus_{k \geq 0} V^*_{k\lambda}
\]

as a \( G \)-module. Since \( \mathbb{C}^\times \)-action specifies one of \( V^*_{k\lambda} \), the restriction \( V^*_{k\lambda}|_K \) is a multiplicity free \( K \)-module.

Without loss of generality, we can assume that the root system \( \Delta \) is defined with respect to a \( \theta \)-stable maximal torus \( T \). Thus there is a well-defined action of \( \theta \) on the root system \( \Delta \). Since \( B \) is assumed also to be \( \theta \)-stable, \( \theta \) preserves the simple system \( \Pi \), and we easily see that \( \theta(P) \) corresponds to \( \theta(\Phi) \). Put \( \lambda^\theta = \sum_{\alpha \in \theta(\Phi)} c_{\alpha} \omega_{\alpha} \). Under an obvious notation, we conclude that

**Lemma 5.4.** The product of partial flag varieties \( \mathfrak{X}_P \times \mathfrak{X}^\theta_P \) is \( G \)-spherical if and only if \( V_{k\lambda} \otimes V_{\ell\lambda}^\theta \) decomposes multiplicity freely as a \( G \)-module for any non-negative integers \( k, \ell \geq 0 \).

The proof is the same as Lemma 5.3 (and essentially, this follows from the lemma if we consider \( G = G \times G \) and \( K = \Delta(G) \)).

Thus we can reinterpret Theorem 5.2 as follows.

**Corollary 5.5.** Let \( P \) be a parabolic subgroup containing a \( \theta \)-stable Borel subgroup \( B \) of \( G \), and we assume the notations above. If the tensor product \( V_{k\lambda} \otimes V_{\ell\lambda}^\theta \) is a multiplicity free \( G \)-module for any non-negative integers \( k, \ell \geq 0 \), then the restriction \( V_{m\lambda}|_K \) decomposes multiplicity freely as a \( K \)-module for any \( m \geq 0 \).

### 5.2. Maximally split parabolic in a real form.

Let \( g_\mathbb{R} \) be a real Lie algebra which is a real form of \( g \). Let \( G_\mathbb{R} \) be a connected analytic Lie subgroup in \( G \) corresponding to \( g_\mathbb{R} \), and we assume it is non-compact. Choose a maximal compact subgroup \( K_\mathbb{R} \) of \( G_\mathbb{R} \). Then we have a Cartan decomposition \( g_\mathbb{R} = k_\mathbb{R} \oplus s_\mathbb{R} \) corresponding to \( K_\mathbb{R} \). It is well known that, for a symmetric pair \((G, K)\), there always exists such a non-compact Riemannian symmetric pair \((G_\mathbb{R}, K_\mathbb{R})\), and our involution \( \theta \) coincides with the complexification of the Cartan involution associated to \( G_\mathbb{R}/K_\mathbb{R} \).

Choose a maximal abelian subspace \( a_\mathbb{R} \) in \( s_\mathbb{R} \). Then a choice of a positive
system of the restricted root system $\Sigma(g^*_R, a^*_R)$ determines a real parabolic subalgebra $p^*_R$ which is maximally split in $g^*_R$. Let $p_{\text{min}}$ be the complexification of $p^*_R$, and $P_{\text{min}}$ the corresponding complex parabolic subgroup of $G$. We denote by $X_{P_{\text{min}}} \cong G/P_{\text{min}}$ a partial flag variety of parabolic subgroups conjugate to $P_{\text{min}}$ as usual.

**Lemma 5.6.** The dense open $K$-orbit in $X_{P_{\text{min}}}$ is isomorphic to $K/M$, where $M = Z_K(a)$ is the centralizer of $a = \mathbb{C} \otimes_R a^*_R$ in $K$.

**Proof.** This lemma is well known, but we prove it for the sake of self-containedness. Since $K \cap P_{\text{min}} = M$, the $K$-orbit through $p_{\text{min}} \in X_P$ is isomorphic to $K/M$. The complex dimension of $K/M$ is equal to the real dimension of Iwasawa’s $n^*_R$, which is also equal to the dimension of $X_{P_{\text{min}}}$. Thus, the orbit must be an open orbit. 

The following is a corollary to Theorem 5.2.

**Corollary 5.7.** Let $P_{\text{min}}$ be the complexification of a maximally split parabolic subgroup of $G^*_R$ as above. If $X_{P_{\text{min}}} \times X_{P_{\text{min}}}$ is a $G$-spherical variety, then $K/M$ is a spherical $K$-variety.

**Proof.** If $X_{P_{\text{min}}} \times X_{P_{\text{min}}}$ is a $G$-spherical variety, then $X_{P_{\text{min}}}$ is a spherical $K$-variety by Theorem 5.2 (note that we can choose a $\theta$-stable parabolic from $X_{P_{\text{min}}}$ so that $X_{P_{\text{min}}} = X_{P_{\text{min}}}^\theta$). So there are finitely many $S$-orbits, where $S$ is a Borel subgroup of $K$. Since $K/M$ is an open orbit in $X_{P_{\text{min}}}$, there are only finitely many $S$-orbits in $K/M$, which implies $K/M$ is $K$-spherical. 

We have a partial converse to the above corollary.

**Proposition 5.8.** The $K$-variety $K/M$ is spherical if and only if $X_{P_{\text{min}}} \times Z_Q$ contains finitely many $K$-orbits for any parabolic subgroup $Q$ of $K$.

Note that if $(K, M)$ is a symmetric pair, then $K/M$ is spherical.

**Proof.** Let $B \subset G$ be a $\theta$-stable Borel subgroup such that $S := K \cap B$ is a Borel subgroup of $K$. We can consider the Borel subgroup $S$ instead of $Q$ without loss of generality. The variety $K/M$ is $K$-spherical if and only if there exists an open $S$-orbit on $K/M$. By Lemma 5.6, $K/M$ is an open $K$-orbit in $X_{P_{\text{min}}}$. So the open $S$-orbit in $K/M$ turns out to be an open $S$-orbit in $X_{P_{\text{min}}}$, which means $X_{P_{\text{min}}}$ is a spherical $K$-variety. Thus we have finitely many $S$-orbits on $X_{P_{\text{min}}}$. Through the isomorphism $K \backslash (X_{P_{\text{min}}} \times Z_S) \cong S \backslash X_{P_{\text{min}}}$, we conclude that $X_{P_{\text{min}}} \times Z_S$ also contains finitely many $K$-orbits. 

6. Double flag varieties of type A

Let us consider a group $G$ of type A. There are three types of symmetric pairs $(G, K)$, denoted by AI, AII, AIII (see [Hel78, § X.6]). Namely they are $\text{SL}_n/\text{SO}_n$, ...
SL_{2m}/Sp_{2m}, and GL_n/GL_p \times GL_q (n = p + q). We will construct examples of double flag varieties with finitely many $K$-orbits, using Theorem 3.1.

Recall the notation $P_\lambda$ for an (upper triangular) standard parabolic subgroup of $GL_n$ from §2, where $\lambda = (\lambda_1, \ldots, \lambda_\ell)$ is a composition of size $n$. In fact, $P_\lambda$ is realized as the stabilizer of a partial flag of subspaces in $\mathbb{C}^n$ of dimension $\lambda_1, \lambda_1 + \lambda_2, \ldots, \lambda_1 + \cdots + \lambda_\ell$.

6.1. Type AI and AII.

Let $G/K = SL_n/SO_n$ ($n \geq 3$) or $G/K = SL_{2m}/Sp_{2m}$ ($m \geq 2$). In these cases, a mirabolic parabolic subgroup is not conjugate to a $\theta$-stable parabolic subgroup. So we have less possibilities to apply Theorem 3.1.

**Proposition 6.1.** Let $(G, K) = (SL_n, SO_n)$ or $(G, K) = (SL_{2m}, Sp_{2m})$, which is a symmetric pair of type AI or AII respectively. If $P \subset G$ and $Q \subset K$ are a pair of parabolic subgroups among the following list (1)—(2), then there are finitely many $K$-orbits in $X_P \times Z_Q$.

1. $P$ is a maximal parabolic subgroup of $G$, and $Q$ is an arbitrary parabolic subgroup of $K$.
2. Assume that $n \geq 4$ is an even integer if $(G, K) = (SL_n, SO_n)$. $P = P_\lambda$ is a parabolic subgroup of $G$ with $\ell(\lambda) = 3$ (i.e., $\lambda = (\lambda_1, \lambda_2, \lambda_3)$), and $Q$ is a Siegel parabolic subgroup of $K$. Here we say $Q$ is a Siegel parabolic subgroup if it is the stabilizer of a maximal isotropic space.

**Proof.** Here we only give a proof for type AI. The proof for type AII is similar.

1. Type $D_{r+2}$ in Theorem 2.2 implies the result.
2. Put $n = 2m$. We use type $E_6$ in Theorem 2.2. Since the maximal parabolic $P'$ in the list should be $\theta$-stable, it must be a parabolic subgroup of $SL_{2m}$ corresponding to a partition $(m, m)$. So we can take $Q = P' \cap K$ as a Siegel parabolic of $SO_{2m}$ with an appropriate choice of conjugates of $P'$.

6.2. Type AIII.

$G/K = GL_n/GL_p \times GL_q (n = p + q)$.

We get three cases in which the double flag variety $X_P \times Z_Q$ has finitely many $K$-orbits. These are direct consequence of Theorem 3.1.

**Proposition 6.2.** Let $G/K = GL_n/GL_p \times GL_q$ be a symmetric space of type AIII. Let $P$ be a parabolic subgroup of $G$ and $Q$ that of $K$. If $P$ and $Q$ are among the following list (1)—(3), then there are finitely many $K$-orbits in $X_P \times Z_Q$.

1. $P$ is any parabolic subgroup of $G$, and $Q = Q_1 \times Q_2$ is a parabolic subgroup of $K$ which satisfies (i) $Q_1$ is of partition type $(1, p - 1)$ and $Q_2 = GL_q$; or (ii) $Q_1 = GL_p$ and $Q_2$ is of partition type $(q - 1, 1)$.
2. $P$ is a maximal parabolic subgroup of $G$, and $Q$ is any parabolic in $K$.
3. $P = P_\lambda$ is a parabolic subgroup of $G$ which corresponds to a composition $\lambda$ with $\ell(\lambda) = 3$ and $Q$ is a maximal parabolic subgroup of $K$.

**Proof.** For (1), We use type $S_{q,r}$ in Theorem 2.2. For (2), we use type $D_{r+2}$
Few remarks are in order. In Case (1) in the above theorem, \( Z_Q \) is isomorphic to a projective space \( \mathbb{P}(\mathbb{C}^p) \) or \( \mathbb{P}(\mathbb{C}^q) \). We call these double flag varieties “mirabolic” after [Tra09] and [FGT09].

In Case (2), if \( P = P_{(m,n-m)} \), \( X_P \) is a Grassmannian Grassm \( m \times n \) of \( m \)-dimensional subspaces in \( \mathbb{C}^n \) \( (n = p + q) \). Thus the action of \( K = \text{GL}_p \times \text{GL}_q \) on Grassm \( m \times n \times X_{Q_1^{GL_p}} \times X_{Q_2^{GL_q}} \) has finitely many orbits with obvious notations.

If \( P = B \) is a Borel subgroup of \( G \), we are able to give a complete classification of the double flag variety \( X_B \times Z_Q \) of finite type for a symmetric pair of type AIII.

**Theorem 6.3.** Let \( G = \text{GL}_n \) and \( B \subset G \) be a Borel subgroup; \( K = \text{GL}_p \times \text{GL}_q \) with \( p + q = n \), \( q \geq p \geq 1 \); and \( Q^1 \) is a parabolic subgroup of \( \text{GL}_p \) and \( Q^2 \) is that of \( \text{GL}_q \). Put \( Q = Q^1 \times Q^2 \) a parabolic subgroup of \( K \). Then there are only finitely many \( K \)-orbits on \( X_B \times Z_Q \) if and only if \( Q^1 \) and \( Q^2 \) are in the following table.

<table>
<thead>
<tr>
<th>Case</th>
<th>( p )</th>
<th>( Q^1 )</th>
<th>( Q^2 )</th>
<th>( Z_Q )</th>
</tr>
</thead>
<tbody>
<tr>
<td>(i)</td>
<td>arbitrary</td>
<td>( \text{GL}_p )</td>
<td>( \text{GL}_q )</td>
<td>{point}</td>
</tr>
<tr>
<td>(ii)</td>
<td>arbitrary</td>
<td>( \text{GL}_p )</td>
<td>mirabolic</td>
<td>( \mathbb{P}(\mathbb{C}^q) )</td>
</tr>
<tr>
<td>(iii)</td>
<td>1</td>
<td>( \text{GL}_1 )</td>
<td>arbitrary</td>
<td>( \text{GL}_q/Q^2 )</td>
</tr>
<tr>
<td>(iv)</td>
<td>2</td>
<td>( \text{GL}_2 )</td>
<td>maximal</td>
<td>Grassm ( \mathbb{C}^q )</td>
</tr>
<tr>
<td>(v)</td>
<td>arbitrary</td>
<td>mirabolic</td>
<td>( \text{GL}_q )</td>
<td>( \mathbb{P}(\mathbb{C}^p) )</td>
</tr>
</tbody>
</table>

Here the second column indicates the condition on \( p \).

**Proof.** We use Theorem 3.4. Let \( \lambda \) be a composition of \( p \), and \( \mu \) be that of \( q \). Note that \( (\lambda, \mu) \) is a composition of \( n \). We put \( P^2 = P_{(\lambda, \mu)} \), which is a standard parabolic subgroup of \( G \), and \( P^3 = P_{(p,q)} \), a parabolic subgroup of \( G \) opposite to the standard parabolic \( P_{(p,q)} \). It is easy to check that \( Q = P^2 \cap P^3 \) is a parabolic subgroup of \( G \). Note that \( P_\lambda \) (respectively \( P_\mu \)) is a parabolic subgroup of \( \text{GL}_p \) (respectively \( \text{GL}_q \)). Now we are in the setting of Theorem 3.4, and conclude that \( X_B \times Z_Q \) is of finite type if and only if the triple flag \( X_B \times X_{P_{(\lambda, \mu)}} \times X_{P_{(p,q)}} \) is of finite type. From Theorem 2.2, we deduce the table above.

**6.3. Summary.**

As a summary, we give tables of the double flag varieties with finitely many \( K \)-orbits in Tables 1–3 below. Note that these tables do not exhaust all the cases.

**7. Double flag varieties of type C**

Let us consider a symmetric pair of type C. There are two irreducible symmetric spaces of type C; namely, type CI and CII. So we consider a symmetric space \( G/K = \text{Sp}_{2n}/\text{GL}_n \) of type CI, or \( G/K = \text{Sp}_{2n}/\text{Sp}_{2p} \times \text{Sp}_{2q} \) of type CII \( (n = p + q) \) in this section.

</table>
First, recall the notation $P_\lambda$ of a standard parabolic subgroup of $Sp_{2n}$ from §2, where $\lambda$ is a composition of size $2n$. The parabolic $P_\lambda$ is realized as the stabilizer of a partial flag of isotropic subspaces in $C^{2n}$. In particular, a maximal parabolic subgroup $P_{(m,2n-2m,m)}$ ($0 < m \leq n$) is the stabilizer of an isotropic subspace of dimension $m$.

If $m = n$, then a totally isotropic subspace of dimension $n$ is called Lagrangian, and we denote by $LGrass(C^{2n})$ the Grassmannian of all the Lagrangian subspaces in $C^{2n}$. Let $P_{(n,n)}$ be a Siegel parabolic subgroup, which fixes a Lagrangian subspace. Since $G = Sp_{2n}$ acts on $LGrass(C^{2n})$ transitively, we have $G/P_{(n,n)} \simeq LGrass(C^{2n})$.

If $m < n$, let $IGrass_m(C^{2n})$ be the Grassmannian of isotropic subspaces of fixed dimension $m$. As in the case of the Lagrangian Grassmannian, we can identify $G/P_{(m,2n-2m,m)} \simeq IGrass_m(C^{2n})$. Note that, if $m = 1$, this reduces to $G/P_{(1,2n-2,1)} \simeq \mathbb{P}(C^{2n})$.

Theorem 3.1 gives us several examples of double flag varieties of finite type.

Proposition 7.1. Let $G/K = Sp_{2n}/GL_n$ be a symmetric space of type CI or $G/K = Sp_{2n}/Sp_{2p} \times Sp_{2q}$ of type CII ($n = p + q$). If a pair of parabolic subgroups $P \subset G$ and $Q \subset K$ is among the following list (1)–(3), then the double flag variety $X \times Z \subset P_{X} \times Z_{Q}$ is of finite type.

(1) $P = P_{(n,n)}$ is a Siegel parabolic subgroup of $G$, and $Q \subset K$ is an arbitrary parabolic subgroup.

(2) $P = P_{(1,2n-2,1)}$ is a maximal parabolic subgroup of $G$, and $Q \subset K$ is an arbitrary parabolic subgroup.

(3) Let us assume that $G/K = Sp_{2n}/Sp_{2p} \times Sp_{2q}$ is of type CII. $P = P_{(m,2n-2m,m)}$ ($1 < m < n$) is a maximal parabolic subgroup of $G$, and $Q \subset K$ is a product of Siegel parabolic subgroups in $Sp_{2p}$ and $Sp_{2q}$.

Proof. For (1), we use type $Sp_{D_{r+2}}$ in Theorem 2.3 and apply Theorem 3.1. Similarly, for (2), we use type $Sp_{Y_{4,r}}$ in Theorem 2.3, and for (3), we use $Sp_{E_6}$. ■

As a summary, we give tables of the double flag varieties of type C with finitely many $K$-orbits in Tables 4–5 below. Note that these tables do not exhaust all the cases.

Table 4: Type CI : $G/K = Sp_{2n}/GL_n$ ($n \geq 2$)

<table>
<thead>
<tr>
<th>$P$</th>
<th>$Q$</th>
<th>$X_P$</th>
<th>$Z_Q$</th>
</tr>
